---

[1] See footnote, p. 54.

[47] Data relate to all land-line employees except those compensated on a commission basis. Excludes general and divisional headquarters personnel, trainees in school, and messengers.

[48] Source: U.S. Interstate Commerce Commission. The averages are those of employees classified and reported to the Commission on an hourly basis (excluding most of the executive, professional, and supervisory employees). The count of employees used in computing weekly hours and weekly earnings is the number on the pay rolls during the month. Hourly earnings were computed by dividing total pay rolls by total man-hours paid for.

Figures of hours and earnings for class I steam railroads comparable to those beginning in 1932 are available also for the years 1921 to 1931. Those are given below. The averages for 1921 to 1927 include hourly rated employees of class I switching and terminal companies but the averages are virtually identical with the averages when these companies are excluded.

Year	Average weekly earnings	Average weekly hours	Average hourly earnings (cents)
1921 (July-Dec.)	$25.87	43.4	59.6
1922	26.70	45.4	58.8
1923	26.65	45.4	58.7
1924	26.37	44.1	59.8
1925	26.91	44.4	60.6
1925	27.12	44.9	60.4
1927	27.43	44.6	61.5
1928	27.71	44.4	62.4
1929	28.49	44.8	63.6
1930	27.76	43.1	64.4
1931	26.76	41.1	65.1

[49] Average for year not available because new series was started in April.

[50] The annual average includes retroactive payments not appearing in the monthly averages.

[51] New series; comparable January data are 118.4 cents.

[52] On previously published basis, April averages would be $40.72, 42.9 hours, and 95.2 cents.

[53] Data reflect work stoppages in April and May.

[1] See footnote, p. 54.

[57] Covers all employees engaged in privately financed construction at the site; ex-ludes employees of these private contractors engaged on publicly financed projects and ff-site workers who are covered by the totals in tables A–1 and A–2.

[58] Includes general contracting as well as general building maintenance and other special building data, 1934 through 1944.

[1] See footnote, p. 54.

[59] Includes projects other than highway and street construction by contractors whose major activity is highway and street work.

Adjusted Hourly Earnings

Adjusted average hourly earnings of production workers in manufacturing industry for 1941–47 are computed by the Bureau of Labor Statistics from the gross average hourly earnings shown in table C–1. Gross average hourly earnings are affected by overtime payments, shift differentials, and production bonuses. In making this adjustment, the influence of overtime has been eliminated on the assumption that it is paid for at one-and-a-half times the straight-time rate for hours in excess of 40 a week. Although shift differential payments, production bonuses, overtime rates based on a workweek which is other than 40 hours, and the payment of double time for overtime, Sundays, or holidays also affect the estimated straight-time hourly earnings, these factors are of less importance in the aggregate, and no correction is made for them in the formula used. The adjustment method is described in the November 1942 issue of the Monthly Labor Review (p. 1053).

In table C–2, gross and adjusted average hourly earnings are shown for all manufacturing industries combined and for durable- and nondurable-goods industry divisions on the basis of the current distribution of total man-hours among industry groups.

In response to requests for summary information on general wage levels in United States industry, the Bureau of Labor Statistics has prepared estimates in six different years of the distribution of production workers in manufacturing industries by straight-time hourly earnings. Such estimates were made in 1941, 1942, 1943, 1945, 1946, and 1947 and are shown in table C–3.[1]

For 1941, 1942, and 1943, the basis of the estimates was the detailed wage-rate distribution in manufacturing industries that had been studied over a period of about 4 or 5 years preceding World War II. Each study yielded straight-time hourly earnings for individual wage earners in the form of a frequency distribution. Each distribution was then adjusted to reflect wage levels prevalent in a recent period (a common period being used in all cases): (1) by allowance for minimum wage regulations that had become effective between the date of the study and the period under consideration; and (2) by a percentage based on the relationship between the straight-time average hourly earnings for all factory wage earners in the industry at the time the particular study was made (plus any allowance for minimum wage regulation) and the estimated straight-time hourly earnings prevailing in the more recent period.

Estimated straight-time hourly earnings were derived from the Bureau of Labor Statistics monthly series of gross average hourly earnings (see table C–1), roughly adjusted to eliminate the influence of overtime and premiums for late shifts.[2] (The data in table C–2 were adjusted to eliminate premium overtime pay only.) The adjusted distributions were then classified according to major industry group, and were used to estimate the distribution of wage earners of the entire industry group; appropriate weighting and adjustments were made to compensate for other individual industries within the group for which no detailed information had been obtained. In turn, the major group distributions were weighted by estimated employment and combined to yield the estimated distribution for all manufacturing.

The summer of 1945 estimates were made by the same basic methods that were used in making those for 1943. Except for two major groups, lumber and machinery, for which more recent distributions were available, the same basic data were used.

The October 1946 and July 1947 estimates included a variety of new material that had become available from studies conducted in 1945, 1946, and 1947. However, the adjustment procedure was quite similar to that used in earlier estimates. The trend of urban wage rate studies (see tables C–5 and C–6) furnished additional information on both the extent and type of wage changes that had occurred between the time of the individual detailed studies and the date of the distribution. By utilizing these new materials together with the adjusted hourly earnings from the monthly series, it was possible to make adjustments more closely following the actual pattern of changes. For the industry groups in which substantial numbers of workers were in industries that had not been studied in recent years the same procedure was used as in the preparation of the 1945 estimates.

---

[1] For more detailed information regarding these estimates, see Monthly Labor Review, June 1942, pp. 1278–1282; October 1943, pp. 637–649; September 1945, pp. 529–530; July 1947, pp. 47–49.

[2] Overtime payments were eliminated by the method described in the November 1942 issue of the Monthly Labor Review, Elimination of Overtime Payments from Gross Hourly Earnings. Shift premiums were estimated in only a few industries where they constitute a significant addition to earnings.

Straight-time average hourly earnings of employees of class I steam railroads that are shown in table C–4 for 1921–47 are compiled regularly by the Interstate Commerce Commission. Coverage extends to those employees who are paid on an hourly basis (excluding major executive, professional, and supervisory employees). Methods of computation are explained in the footnotes to the table.

TABLE C–2: Estimated average hourly earnings, gross and exclusive of overtime, of production workers in manufacturing industries, 1941–47[1]

In cents]

Period	All manufacturing		Durable goods		Nondurable goods	
	Gross	Excluding overtime	Gross	Excluding overtime	Gross	Excluding overtime

---

[1] In making the adjustment, work in excess of 40 hours per week is excluded; it is regarded as overtime paid for at time and one-half. The method of estimating average hourly earnings exclusive of overtime makes no allowance for special rates of pay for work done on major holidays. Data for the months of January, July, September, and November, therefore, may not be precisely comparable with data for the other months in which important holidays are seldom included in the reported pay period.

[2] Owing to the 2-day holiday in August 1945, in celebration of the Japanese surrender, that month's estimate was not released, and consequently the average for the year 1945 is for 11 months.

TABLE C–3: Estimated distribution of production workers in manufacturing industries, by straight-time hourly earnings, selected periods, 1941–47

Straight-time hourly earnings	Distribution of production workers											
	January 1941		January 1942		June 1943		Summer 1945		October 1946		July 1947

[1] Included in the "40 and under 50 cents" class; only a few workers received less than 40 cents.

[2] Not available.

[3] Includes workers earning $1.30 or more.

[4] Includes workers earning $1.60 or more.

[5] Includes workers earning $1.70 or more.

[6] Less than one-half of 1 percent.

NOTE: For more details see Monthly Labor Review, June 1942, pp. 1278–1282 October 1943, pp. 637–649; September 1945, pp. 529–530; July 1947, pp 47-49.

TABLE C-4: Straight-time average hourly earnings[1] of employees of class I steam railroads, 1921–47

[1] The averages cover employees classified and reported to the Interstate Commerce Commission on an hourly basis (excluding major executive, professional, and supervisory employees).

[2] To obtain the averages for 1921 to 1927, compensation for "straight-time actually worked" was divided by hours of "straight-time actually worked" as classified by the Interstate Commerce Commission. For 1928 to 1947, compensation for "straight-time paid for" was divided by hours of "straight-time paid for." The two methods give almost identical results.

[3] July—December.

[4] Including class I switching and terminal companies. The Interstate Commerce Commission published detailed data for the various groups of employees up to 1927 only for class 1 railroads including switching and terminal companies and thereafter only for these roads excluding switching and terminal companies. The exclusion of these companies makes virtually no difference in the averages for the industry as a whole.

[5] Customarily premium pay for overtime begins in railroad employments after 48 hours per week. Part of the increases in wages in 1943 and 1944 was "in lieu of claims for time and one-half pay for time worked over 40 hours per week."

Wage Rates

Urban Wage Rates

The index of urban wage rates was established by the Bureau of Labor Statistics in October 1943 to provide a dependable measure of changes in basic wage rates that is unaffected by such variables as premium pay for overtime and late-shift work, interindustry and interregional shifts of employment, changes in occupational structure, and changes in weekly hours of work. The index reflects the effect of general changes in occupational wage-rate levels, including individual wage adjustments in establishments that do not have formal rate structures. Changes in incentive earnings resulting from variations in output and changes in the prevalence of incentive pay also affect the index, as it has not been practicable to segregate these variables. Likewise, merit increases and automatic progressions within rate ranges—which are believed to be of minor importance—influence the series.

The series show the movement of wage rates (1) in manufacturing industry as a whole and for a selected group of nonmanufacturing industries; (2) in different manufacturing and nonmanufacturing industry groups; (3) in nine economic regions for all manufacturing and for total selected nonmanufacturing (discontinued after April 1945); and (4) in 28 selected cities each having 250,000 or more population, for both the manufacturing and total selected nonmanufacturing groups.

Although the survey was first made in October 1943, manufacturing figures were projected backward to include April 1943, October 1942 (beginning of the period of World War II wage stabilization), and January 1941 (base period of little steel formula); and nonmanufacturing figures to include April 1943.

The urban wage rate is the average of hourly wage rates (average hourly earnings, including straight-time pay of incentive workers) in selected occupations, exclusive of all premium pay for overtime and for work on second and third shifts. The series are described as urban because typically rural industries have little representation in the index.

Selected key occupational wage statistics gathered semiannually from about 6,600 identical establishments in 69 separate labor-market areas in the 48 States form the basis of the index. The 69 areas included in the constant sample were chosen because of the wide variety of their industries, the importance of their dominant industries in the respective regions, and the representative nature of the areas with respect to regional wage levels. Each area contains one or more cities of 25,000 population or larger. Together, they had about 40 percent of the Nation's population and 70 percent of the urban population when the series were established in the fall of 1943.

The manufacturing industries covered in each area—typically 10 to 15—were selected as characteristic of the area represented; for the most part they are the larger industries which tend to dominate the wage-movement pattern in their respective communities. In contrast, the same nonmanufacturing industries were included in the series for all areas. They include about 10 industries representing 5 broad groups: (1) finance, insurance, and real estate; (2) retail trade; (3) wholesale trade; (4) local public utilities; and (5) services.

Suitable weight is assigned to occupations, industries, and industry groups within the labor-market area and economic region, as well as to large and small cities within the region. By using constant weights, the influence of each occupation (and each sex within each occupation), industry, and area is held constant in all periods.

Wage-rate changes in an establishment are measured in terms of changes in selected key jobs. These jobs—usually 10 or 12 in number—are uniform within a given industry and are considered representative of the various sex and skill groups and wage levels characteristic of the industry. Office and clerical jobs are covered only in the occupations for nonmanufacturing industries.

Percentage changes in urban wage rates in manufacturing and nonmanufacturing industries by industry group are shown in table C–5 for selected periods between January 1941 and October 1947.

The percent of change in urban wage rates in manufacturing and in nonmanufacturing industries by area is given in table C–6 for specified periods between April 1943 and April 1947.

TABLE C-5: Percent of change in urban wage rates (manufacturing and selected nonmanufacturing industries), by industry group, selected periods, January 1941–October 1947[1]

Industry group	Percent of change from—											
	Jan. 1941 to Oct. 1942	Oct. 1942 to Apr. 1943	Apr. 1943 to Oct. 1943	Oct. 1943 to Apr. 1944	Apr. 1944 to Oct. 1944	Oct. 1944 to Apr. 1945	Apr. 1945 to Aug. 1945	Aug. 1945 to Oct. 1945	Oct. 1945 to Apr. 1946	Apr. 1946 to Oct. 1946	Oct. 1946 to Apr. 1947	Apr. 1947 to Oct. 1947[2]

Farm Wage Rates

Annual farm wage rates from 1910 to 1922 in table C–7 are geographic division averages of rate data received each year by the Bureau of Agricultural Economics of the United States Department of Agriculture from crop reporters. They give average rates per day and per month paid in their locality, with and without board. During 1910–22, the persons reporting were asked to state the wage rates per day "at harvest" and for "other than harvest" labor.

Beginning in 1923, farm wage-rate inquiries have been made quarterly on the first of January, April, July, and October, and the quarterly wage rates have been combined to obtain annual wage rates. Use of the quarterly survey tended to eliminate the need for a distinction between wage rates for harvest hands and for other than harvest labor.

In the quarterly inquiry, the "average wage being paid to hired labor at the present time in your locality" is requested. Reports for the four types of cash payments continued, as before 1923, to be those per day and per month, with and without board.

Crop reporters are instructed to include in their estimates of day rates "the average daily earnings of piece workers", but it is doubtful that the series on day rates reflect completely the level of day-rate equivalents of piece rates or of rates paid workers hired through labor contractors. Independently collected data indicate that nearly half of the hired farm workers employed in the fall harvest are paid piece rates. It seems likely that the day and month rates reported by crop reporters are usually those paid to able-bodied, experienced hired workers, rather than the averages which include the wages paid inexperienced men or those paid women or children doing hired farm work. The rates reported probably provide a fairly accurate picture of average rates paid regular hired men in the general crop-producing and dairying regions.

Hired farm-worker employment is the basis for weighting wage rates tabulated by States to obtain rates for geographic divisions and the United States. The annual average employment based on census and labor requirements data was used for weighting purposes in the period 1910 to 1922. From 1923 to 1938, quarterly wage rates were weighted by quarterly averages of employment derived from data supplied by crop reporters. From 1939 to date, the appropriate current monthly estimates of hired farm workers have been used to weight the quarterly wage rates.

The composite wage rate is the average of the rates shown for the four methods of payment, weighted by the estimated numbers of workers receiving the different types of payment in the various geographic divisions. The rates per day are multiplied by 20 to obtain their monthly equivalents. A constant set of percentages of the workers receiving each type of rate, based on a special study made in 1927, has been used in weighting for each geographic division from 1925 to date.

As reporting is voluntary, the quarterly wage-rate sample is somewhat selective. The series is based upon reports from farmers employing more than average amounts of farm labor. Although returns are received from nearly all the agricultural counties in the country, most of the returns are from operators of general crop and livestock farms. The prevailing wage rates on fruit, truck, and similar specialized farms are reflected only to the extent that regular crop correspondents give adequate consideration to them in reporting the average wage rates for their localities.

The sample of farmers reporting each month varies from 17,000 to 21,000. The Census of Agriculture reported 5,859,169 farm operators in the United States in 1945.

Farm wage-rate data are shown for 1910–47 in table C–7 for the United States and individual geographic divisions.

NOTE: In addition to the figures shown in table C–7 based on the collection of crop-reporter data, the Bureau of Agricultural Economics initiated an expanded program of farm wage statistics in 1945, including collection of data through enumerative sample surveys. These occasional surveys include collection of information on wages and wage rates paid hired farm workers employed during a specified week in a national sample of about 20,000 farms.

There are important differences between the wage data collected in these surveys and the crop-reporter series. One of the most important differences is that wages and related information are obtained from the farmer for each hired worker employed on his farm during the reporting week. Thus, the farmer provides data on something that actually has occurred on his farm, which he can report more accurately than the level of wages on all farms in the locality. Another important difference is that all types of wage rates and all types of hired farm workers are covered. The new series contain data on receipt of major perquisites and on wages and time worked on the reporting farm during the week as well as on the cash wage rate. Comparisons of hourly, daily, or weekly cash wages earned are possible for workers paid different types of rates and for different groups of workers, as for regular and seasonal workers. Comparisons are also possible of daily wage costs on different types of farms within the major regions of the United States.

The new surveys have not been in operation long enough to provide historical series such as those assembled for the main tables of this Handbook of Labor Statistics. Data from the new farm wage surveys are published by the Bureau of Agricultural Economics in the series entitled Surveys of Wages and Wage Rates in Agriculture.

TABLE C–7: Wage rates of hired farm workers, total and geographic divisions, 1910–47

Period[1]	United States average wage rate				Composite wage rate per month[2]

[1] Quarterly reports are for the first day of the reporting month.

[2] Weighted average of monthly rates with and without board, and daily rates with and without board converted to a monthly basis. Composite farm wage rates are an approximate measure of the trend of farm wages; but because of the extreme diversity of the wage rates that enter into the composite and the exclusion of the value of perquisites, this rate has limited validity as a measure of actual wage levels.

Union Scales of Wages and Hours

Trends in union wage rates and hours are measured annually by the Bureau of Labor Statistics in national surveys covering building construction, printing, baking, trucking, and local transit. The annual reports also give the scales in effect in particular trades and cities. As the statistics deal exclusively with union scales, they may or may not reflect scales generally prevailing in a locality, depending upon the extent of local union organization in that locality.

A union scale is a minimum wage rate or a maximum schedule of hours agreed upon by negotiation between employers and trade-unions. Rates in excess of the agreed minimum, although frequently paid in reward for long service, for special qualifications, or for personal or other reasons are not used in the computations. Scales applying to apprentices are also excluded.

Union scales for the various trades included in the industries studied were obtained directly from officials of the local trade unions concerned, and where feasible, the data were obtained by mail questionnaire.

The series for the building and printing industries were started in 1907. From a coverage of 39 cities in the early years, the total increased to 75 cities having populations of from 40,000 to 1 million and over in 1941. The occupational coverage also increased in the same period from 14 to 27 journeymen and from 4 to 10 helpers and laborers trades in building construction and from 7 to 11 book and job and from 4 to 8 newspaper classifications in the printing industry. The local transit series started with 1929, that for trucking with 1936, and that for baking with 1939. The survey date which was originally May 15 was changed to June 1 in 1938 and to July 1 in 1942.

In all, 64 trades or subdivisions of trades were covered in the five industries on July 1, 1946. Coverage extended to about one-fourth of the estimated building construction workers, about one-third of the printing workers, one-fifth of the bakery workers, and two-fifths of the streetcar and bus operators employed in July 1946. A similar estimate is not currently available for truck drivers because their employment crosses numerous industry classifications.

The index, utilized for trend determination purposes, links data obtained for each pair of years and may be termed a "chain" index. Year-to-year changes are computed from aggregates of the scales of unions furnishing such data for identical classifications in two consecutive years. The active membership, utilized as a weight in both of the aggregates used for each year-to-year comparison, is that reported for the second year. The total of the current aggregates (membership times rate) is then divided by the total of the previous year's aggregates. The ratio so obtained, multiplied by the previous year's index number, becomes the current index number.

Originally, 1907 was the base year of the index series. Subsequently, the base period was changed to 1913. When the series were revised in 1936 a shift was made to 1929 as the base. In 1944, the series were revised using the year 1939 as the base period. That year was selected for basing purposes to give the series greater currency and because it was a period unmarked by unusual economic fluctuations. The indexes are limited to the movement of basic scales and consequently are not intended to measure such factors as movement of earnings or take-home pay.

Indexes of hourly wage rates and weekly hours of union members are shown for selected industries in table C–8 by years from 1907 through 1947. The average hourly rates of union workers in selected building-construction trades in 37 cities appear in table C–9, which covers selected years between 1910 and 1947.

TABLE C–8: Indexes of union hourly wage rates and weekly hours in selected industries and trades, 1907–47

[1939 = 100]

Rates for 1910, 1920, and 1930 were those effective on May 15; beginning in 1940 the survey covered June 1; in 1945, 1946, and 1947, the survey date was July 1.

[2] Work stoppage on July 1, 1947.

Net Spendable Weekly Earnings

The published averages of weekly earnings in manufacturing industries (see table C–1) have been adjusted by the Bureau of Labor Statistics to show spendable income of workers after the payment of personal income taxes. Before the extension of income taxes to the lower income brackets in recent years (see changes in table L–9), the only Nation-wide deduction from gross weekly pay was the social-security tax of 1 percent of annual income up to $3,000, which became effective, January 1, 1937.

The amount of tax liability depends on the number of dependents supported by the worker as well as on the level of his gross income. Therefore, the tax liability has been computed for two types of income receivers: (1) A worker supporting an adult and two children; and (2) a single person with no dependents. Income taxes on annual income are computed for the two types of income receivers by using Internal Revenue Form 1040 (long income tax form) and applying to it allowances for deductible expenses, personal exemption, credit for dependents, and earned income credit provided by Internal Revenue Income Tax Form 1040A (short income tax form). Allowances made for deductible expenses are 6 percent of annual income for years prior to 1944 and 10 percent for subsequent years. These deductible expenses are subtracted from annual income to obtain net income. All income is considered to be earned, within the limits provided by law, for the purpose of determining earned-income credit which is estimated at 10 percent of net income in the years in which such credit was allowed. The normal tax and the surtax are then computed by using the rates given in the instructions for filling out Internal Revenue Form 1040 and are combined to obtain the income tax. The defense tax is computed for 1940 and the victory tax for the year 1943. The social-security tax is added to these taxes to obtain total Federal taxes.

Net spendable annual income is then obtained by subtracting these Federal taxes from annual income. Net spendable weekly earnings are computed by dividing net spendable annual income by 52.

To reduce gross weekly earnings to net spendable earnings, income and social security taxes are subtracted from the average weekly earnings by means of formulas derived by the method explained above.

Net spendable weekly earnings are computed from average weekly earnings of $49.17 (August 1947):

For a single worker

$$\$49.17 \times 0.819 + \$1.83 = \$42.10$$

For a family of 4

$$\$49.17 \times 0.819 + \$7.31 = \$47.58$$

Changes in purchasing power of net spendable weekly earnings are derived by deflating net spendable weekly earnings by the changes in the consumers' price index for moderate income families (see table D–1). In making this adjustment, the year 1939 was used as a base. The consumers' price index applies to family living costs rather than to those for single individuals; no current information is generally available as to the prices of room, board, and restaurant items that are important in the budgets of single persons.

However, to adjust the Consumers' Price Index from a 1935–39 base to a 1939 base, the method is exemplified as follows:

> The August 1947 index of 160.3 (1935–39 = 100) divided by the 1939 index of 99.4 (1935–39 = 100) equals 1.613—the ratio between the Consumers' Price Index in August 1947 and the year 1939—or an index for August 1947 of 161.3 (1939 = 100).

To obtain net spendable weekly earnings expressed in 1939 dollars for August 1947, computations are:

For a single worker

$$\$42.10 \div 1.613 = \$26.11$$

For a family of 4

$$\$47.58 \div 1.613 = \$29.50$$

Net spendable weekly earnings for a single person and a family of four are shown in table C–10, both in current dollars and in terms of 1939 dollars, by months from 1939 to 1947.

TABLE C–10: Gross and net spendable average weekly earnings of production workers in manufacturing industries, in current and 1939 dollars, 1939–47

[Current dollars and 1939 dollars]

Period	Gross average weekly earnings	Net spendable average weekly earnings

Section D: Prices and Cost of Living

Throughout this century, the Bureau of Labor Statistics has been the principal price collection agency of the Federal Government, outside the field of agriculture, and is the only agency of the Federal Government that systematically collects price statistics at manufacturing, wholesale, and retail levels. As a part of its regular work, the Bureau of Labor Statistics has for many years provided basic price information for other governmental agencies, for State and local governments, and for labor and business organizations as a basis for wage and price adjustments. This program currently includes the official United States indexes of wholesale prices, the consumers' price index for moderate-income families in large cities (including retail costs of foods, rents, fuels, and other goods and services), and price checks among consumers.

Consumers' Price Index for Moderate-Income Families in Large Cities

The Bureau of Labor Statistics consumers' price index for moderate-income families in large cities—called "cost of living" index until September 1945—is designed to measure average changes in retail prices of selected goods, rents, and services—weighted by quantities bought by families of wage earners and moderate-income city workers in 1934–36. It indicates, for example, how much more it cost in 1946 than in 1939 to buy the goods typically purchased by a family which in 1934–36 had an income of about $30 a week, and which still lived in the same town, in about the same kind of house. It is a price barometer, not a measure of changes in the total amount families spend for living, which also depends on changes in income and in the manner of living.

The index represents the movement in the prices of living essentials in the family budget—food, apparel, housefurnishings, rent, utilities, fuels, and miscellaneous goods and services such as medical care, personal care, transportation, laundry services, and recreation. Approximately 180 individual items are priced for the index: 61 foods, 39 articles of apparel, 12 kinds of fuel, 21 kinds of housefurnishings, 48 miscellaneous goods and services, and rent. Since two or more qualities are priced for many articles, well over 300 different articles and qualities are used in the computation of the index. In 1934–36, the Bureau of Labor Statistics selected the articles to be priced on the basis of an extensive study of actual expenditures of about 14,500 moderate-income families. Prices for some goods follow the same trends as others. It is not necessary, therefore, actually to collect prices for everything the typical family buys.

The consumers' price index is based upon changes in food prices in 56 cities and changes in prices of all other important goods and services in 34 cities. More than 120,000 food prices are collected each month in 1,750 independent food stores and 275 chain organizations or their branches, representing approximately 8,600 individual stores. Prices for goods and services other than food are obtained from 3,900 stores and service establishments, selected to represent all types of retail outlets which wage earners and other families with moderate incomes patronize. Rental data are obtained directly from tenants in 40,000 dwellings in 34 cities. The number of rental dwellings and stores surveyed in each city varies with the size of the city.

Prices for all articles except coal, gas, and electricity, are collected by personal visits of representatives of the Bureau. Every attempt is made to price goods and services of the same quality from period to period. The agent does not ask for the price of "a medium-priced shirt" but obtains a price from the buyer for a shirt in stock which most nearly answers the detailed description furnished to him by the Bureau. The prices recorded are those actually charged consumers. As a rule the agent, as well as obtaining selling prices and quality information from buyers or department heads, examines the merchandise and checks price tags or listed prices. Prices for coal, gas, and electricity are obtained by mail questionnaires, supplemented by personal visits by agents at least once a year.

In order to give an accurate picture of the effect of changes in retail prices on the family budget, each item priced is given an importance equal to the importance in family purchases of that article or of a group of articles which the priced item represents. Since, for example, bread is more important than cheese and both are more important than bananas, the weighting procedure used in the index to reflect price changes for food items takes into account the difference in family expenditure for these items. Thus, if the prices of bread and of bananas both rise 10 percent, the change in the price of bread has a much greater effect upon the index. The importance of each article priced was determined city by city from the information collected in the 1934–36 survey of expenditures, the same survey from which the list of items to be priced was selected.

The index is calculated as a fixed base weighted aggregate, using prices in 1935–39 as 100. Weights for individual commodities and groups of commodities in each city are based primarily upon family expenditures in that city as shown by the 1934–36 expenditure study, with certain changes necessitated by changed market conditions. Indexes for individual cities are combined to obtain the national average for 34 cities, using weights based upon most recent population data.

NOTE: From June 1944 to January 1947, the Bureau of Labor Statistics with each month's release on the consumers' price index explained that "the index does not show the full wartime effect on the cost of living of such factors as lowered quality, disappearance of low-priced goods and forced changes in housing and eating away from home." This statement was expanded after the report of the President's Committee on the Cost of Living in November 1944, which recommended: "Under the exceptional market conditions which exist in wartime, and so long as we have a seller's market, allowance should be made for a hidden increase in the cost of living of probably as much as 3 and certainly not more than 4 percentage points, due to quality deterioration, disappearance of cheaper goods, decrease of special sales, and increases in under-reporting of prices actually charged."

In December 1945, the Stabilization Director, in connection with Executive Orders No. 9599 and No. 9651, indicated that if account were taken of continued deterioration of quality and unavailability of merchandise between September 1944 and September 1945, the over-all allowance for the period from January 1941 to September 1945 would total approximately 5 points for large and small cities combined. No agency has attempted to take account of quality changes and other hidden factors affecting the consumers' price index since September 1945.

The President's Committee in establishing the original adjustment explained that the disadvantage to a buyer in a seller's market "can be expected to disappear as soon as we can resume full production of consumer goods and services in a competitive market." By the end of 1946, it was evident that several of the factors had disappeared or diminished in importance since the end of World War II, such as the failure to measure adequately over-ceiling food prices. Other factors still remained, and some had increased, such as special rental charges. The Bureau of Labor Statistics had never been able to make any precise estimate of the amount of these adjustments. In fact, the President's Committee noted that the methods applied by its Technical Committee "to estimate the hidden increase in living costs in a seller's market . . . should not be adopted by the Bureau of Labor Statistics."

These adjustments were never included in the consumers' price index, and the Bureau of Labor Statistics after January 1947 dropped the explanation from its reports.

The consumers' price index for moderate-income families in large cities is shown by groups of commodities for the period 1913–47 in table D–1; and in table D–2, this index is shown for selected cities, Territories, and Possessions for 1923–47.

The base period for the consumers' price indexes for all of the data in table D–1 and most of the data in table D–2 is the 5-year average for 1935–39. Bridgeport, Omaha, San Diego, South Bend, and Wichita indexes in table D–2 have June or December 1944 as bases. These five cities mentioned are included in table D–2 with the 34 large cities regularly surveyed for the consumers' price index. The indexes for Alaska have a July 1944 base period; those for Honolulu, March 1943; for Puerto Rico, March 1941; and for the Virgin Islands, October 1943.

Table D–1: Consumers' price index for moderate-income families in large cities, by group of commodities, 1913–47

[1935-39=100]

Period	All items	Food	Apparel	Rent	Fuel, electricity, and ice			Housefurnishings	Miscellaneous
					Total	Gas and electricity	Other fuels and ice

Retail Prices of Foods

Bureau of Labor Statistics indexes showing changes in retail prices for foods normally purchased by moderate-income city families are a component of the consumers' price index for moderate-income families in large cities, described on page 104. Prices for 61 foods are used in computing the indexes. These food prices are obtained monthly by trained representatives of the Bureau from a scientifically selected sample of chain and independent retail food dealers. The survey is made simultaneously in 56 large cities during the first 3 days of the week containing the 15th day of each month.

In order to have the most comparable measure possible from store to store, from time to time, and from city to city, the Bureau's agents use a description defining the quality or grade and the amount of each food for which prices are to be quoted by retailers. Each retailer is asked to quote prices for the brand and size of the specified food he sells in greatest volume.

In the preparation of the indexes, proper weights are given to chain and independent stores as determined by retail sales volume of such stores in each city. The city average prices for these foods are then weighted on the basis of relative amounts of each food normally purchased by families of wage earners and clerical workers to obtain city food indexes. Indexes so obtained are combined by the use of population weights to secure the 56-city average. In addition to the 34 cities included in the consumers' price index (see table D-2), indexes of retail prices of foods for 22 cities during 1923-47 are shown in table D-3. Food indexes are given by groups of food in table D-4 covering 1923-47.

TABLE D-3: Indexes of retail prices of foods in 22 cities, 1923–47

---

[1] For August 1939, the month before World War II started, the indexes were: all foods, 93.5; cereals and bakery products, 93.4; meats, 95.7; dairy products, 93.1; eggs, 90.7; fruits and vegetables, 92.4; beverages, 94.9; fats and oils, 84.5; and sugar, 95.6.

City Worker's Family Budget

In accordance with a directive of the 79th Congress, the Bureau of Labor Statistics determined the annual dollar cost of a worker's family budget and the relative differences between cities, as shown in table D-5. The 34 large cities in the United States which are covered in the Consumers' Price Index were selected for study and the budget was priced for March 1946 and June 1947. The budget includes food, clothing, housing, medical care, transportation, other goods and services, and an allowance for other essential needs such as taxes, insurance, union dues, and charity donations.

The budget represents the estimated cost in dollars for a city worker's family of four persons to maintain an adequate level of living according to prevailing United States standards of the needs for health, efficiency, nurture of children, and participation in community activities. It is neither a "subsistence" nor a "luxury" budget. It provides a modest and adequate American standard of living based upon the kinds and quantities of goods and services that workers actually select.

In formulating the budget, the basic problem was to determine for each group of goods or services the dividing point in consumption between what families considered to be an adequate or an inadequate level of living—the point in the scale of family consumption below which reduction meets greater and greater resistance and above which expansion becomes more and more limited. This was determined by a study of changes in family consumption with changes in purchasing power, as described in the preprint from the Monthly Labor Review for February 1948, Serial No. R 1909, The City Worker's Family Budget. Family expenditure records obtained in earlier Bureau surveys, particularly in 1934–36 and again in 1941 and 1944, were used for this purpose.

The list of items and quantities in the budget was determined under the guidance of a technical committee. In general, existing scientific standards were used. It was necessary to translate these standards into a list of commodities and services usually purchased by American families. For the food budget, a diet was selected which approximates the nutritional standards recommended by the Food and Nutrition Board of the National Research Council. The housing budget meets the standards fixed by the American Public Health Association and by the Federal Public Housing Administration.

Representative articles were priced for March 1946 and June 1947 by personal visit of Bureau of Labor Statistics agents, according to the regular procedure used in pricing for the Consumers' Price Index. However, prices were obtained from more sources and for more items than is usual. For each city actual prices were collected for over 85 percent of the goods and services included in the budget; others were estimated on the basis of established relationships to the prices of other commodities in a few selected cities.

The type of family chosen—in some respects an arbitrary choice—consists specifically of four persons living in a separate house or apartment. Family composition is an employed father aged 38 years, a housewife of 36 not gainfully employed, a boy of 13 in high school, and a girl of 8 in grade school.

Although detailed budget studies have not been made for families of sizes other than four persons, the Bureau of Labor Statistics has made the following estimate of costs:

	Percent of cost for 4 persons
2-person family	65
3-person family	84
5-person family	114

For cities other than those covered in the study, a procedure is available in the Bureau of Labor Statistics for use in estimating the cost of the budget on the basis of a short list of items.

Table D–5: City worker's budget for family of 4 persons and relative differences in costs in 34 large cities, March 1946 and June 1947

[Cost in Washington, D.C. = 100]

City and State	Dollar costs										Relative differences in costs (Washington, D.C. = 100)							
	Estimated total cost of budget		Goods and services		Food[1]		Clothing[2]		Housing[3]		Goods and services		Food[1]		Clothing[2]		Housing[3]

[1] Includes meals and between-meal food and beverages purchased and consumed away from home.
[2] Includes shoe repairs, dry cleaning, and supplies for home cleaning and mending.
[3] Rent, heating fuel, utilities, housefurnishings, and household supplies.

Wholesale Prices

The wholesale price index of the Bureau of Labor Statistics is designed to measure the average change in commodity prices at primary market levels. It is derived from more than 800 price series which are combined into 49 subgroups, 10 major groups, and 5 important economic groups.

In general, the prices used for the index are those charged by representative manufacturers or producers to types of distributors or industrial consumers which are characteristic of the particular industry. Insofar as feasible, prices used for the index are f.o.b. point of production or sale. For farm products and some foods, prices quoted in organized commodity markets are used.

A commodity may be priced at several stages of production. For example, cotton appears in the index as raw cotton, cotton yarn, cotton grey goods, cotton piece goods, and cotton clothing. For each of these stages a representative commodity sample has been selected and prices obtained at the primary market level of distribution.

Commodities are priced in terms of a given specification at stated terms of trade to the type of purchaser accounting for the greatest volume of purchases. Shifts in the relative importance of sales to different types of purchaser or the distribution pattern of the industry, changes in the relative importance of sellers, and major variations in the specification of the commodities are handled so as to cause no movement in the index.

A majority of the more than 800 price series are represented by a single quotation, since for many articles price movements of major producers are closely related. This is not true for about 150 commodities for each of which quotations from 2 to 50 sellers are used. In all, a total of about 1,700 quotations go into the index each period.

If commodities have a recognized market price, quotations are taken from trade journals. For other commodities, including most manufactured goods, prices are obtained directly from sellers.

The index is calculated as a fixed base weighted aggregate, using prices in 1926 as 100. Current weights reflect quantities marketed in 1929–31. These weights have been used since 1934 with minor changes dictated by changing market conditions. Wholesale price indexes by groups of commodities shown in table D–6, cover the period 1890–1947.

TABLE D-6: Indexes of wholesale prices by group of commodities, 1890–1947[1]

[1926=100]

Period	All commodities	Farm products	Foods	Hides and leather products	Textile products	Fuel and lighting materials	Metals and metal products	Building materials	Chemicals and allied products	House furnishing goods	Miscellaneous	Raw materials	Semimanufactured articles	Manufactured products	All commodities other than farm products	All commodities other than farm products and foods

---

[1] Commodity groups covered by the index are: Farm products—grains, livestock and poultry, and other; foods—dairy products, cereal products, fruits and vegetables, meats, and other; hides and leather products—shoes, hides and skins, leather, and other; textile products—clothing, cotton goods, hosiery and underwear, rayon, silk, woolen and worsted goods, and other; fuel and lighting materials—anthracite, bituminous coal, coke, electricity, gas, and petroleum products; metals and metal products—agricultural implements, iron and steel, motor vehicles, nonferrous metals, and plumbing and heating; building materials—brick and tile, cement, lumber, paint and paint materials, plumbing and heating, structural steel, and other; chemicals and allied products—chemicals, drugs and pharmaceuticals, fertilizer materials, mixed fertilizers, and oils and fats; housefurnishing goods—furnishings and furniture; and miscellaneous commodities—automobile tires and tubes, cattle feed, paper and pulp, crude rubber, and other.

Section E: Industrial Relations

By act of Congress, the Commissioner of Labor was "specially charged to investigate the causes of, and facts relating to, all controversies and disputes between employers and employees." Currently, the Bureau of Labor Statistics is the governmental agency which covers the whole field of statistics dealing with work stoppages. Information on trade-union membership and the extent of collective bargaining is also made available by the Bureau. Series of all three types are included in this section. In addition, summaries are presented on the handling of cases by the Conciliation Service of the United States Department of Labor (recently replaced by the independent Federal Mediation and Conciliation Service) and by the National Labor Relations Board.

Membership of Labor Unions

In the absence of official Government statistics covering trade-union membership for the United States, the Bureau of Labor Statistics has combined membership series from reports and statements issued by the trade-union organizations in their official journals, reports, or convention proceedings.

Union membership is defined differently by various unions. However, the totals reasonably reflect year-to-year changes within each major union group.[1]

American Federation of Labor figures are those reported annually by the Federation's secretary-treasurer. These membership data are defined by the AFL as the "total paid membership of the affiliated national and international organizations and the directly chartered trade and federal labor unions" based "on the actual per capita tax" remitted by affiliated unions.

The Congress of Industrial Organizations, which was formally organized in 1938, and existed as a Committee for Industrial Organization from November 1935 to November 1938, has never published a consecutive membership series. The figures shown, therefore, are based upon reports or statements of CIO officials as to total membership or reported gains over a specified period; footnotes indicate sources.

The third broad category of union members consists of those who belong to labor organizations which are not affiliated with either the AFL or the CIO. In general, this group of independent or unaffiliated unions includes all bona fide national labor organizations and excludes those which are either purely local in character or of which the jurisdiction does not extend beyond the employees of a single employer. In addition to the four long-established train- and engine-service railroad brotherhoods, this group includes a relatively large but fluctuating number of small labor organizations. Recent changes in affiliation of certain large labor organizations, such as the United Mine Workers of America and the International Association of Machinists, have also influenced the membership totals of the different groups.

For the period 1897 through 1934, membership figures for the independent or unaffiliated group of labor organizations are those compiled in Ebb and Flow in Trade Unionism.[2] For the period 1929–34, these data have been adjusted to include membership figures, also compiled by Mr. Wolman, covering unions affiliated with the Trade Union Unity League. Data for some unaffiliated unions for the years since 1934 are fragmentary and the totals presented are estimates of the Bureau of Labor Statistics based upon available sources.

In conjunction with membership statistics of the three main groups described above (insofar as available from 1897 through 1947), the number of affiliated unions of the AFL and CIO as compiled from official union sources are also given in table E–1, which gives membership by years 1897–1947. Similar data for independent unions are not available.

---

[1] Many unions which have headquarters in the United States also have locals outside the continental United States, primarily in Canada. Separate statistics of membership, by countries, are not, however, available and the data therefore include a union's total membership irrespective of where located. The Thirty-fifth Annual Report on Labor Organizations in Canada, published by the Canadian Department of Labor and covering the calendar year 1946, reported 573,258 Canadian workers as members of International unions having principal offices in the United States.

Extent of Collective Bargaining

Information on the extent of collective bargaining and the prevalence of union recognition clauses has been made available on a comparable basis by the Bureau of Labor Statistics annually, from 1942 through 1946. During each year, an attempt was made to obtain as many current collective-bargaining agreements as possible. As agreements are supplied voluntarily and no accurate data exist on the number of union agreements, the proportion of agreements actually on file cannot be checked against the number in effect. Union publications, National Labor Relations Board elections, newspapers, and other sources of information on the signing of union agreements or the revision of previous agreements are used. For each agreement, a record is kept of the name of the company, the union, the effective and expiration dates, the industry classification, and the type of union-security clause.

In analyzing union agreements for union security, seven characteristics, which are defined as follows, were considered:[3]

(1) Under the closed shop, all employees must be members of the union at the time of hiring and they must remain members in good standing during their period of employment. Hiring through the union (unless the union is unable to supply the required number of workers within a given period) is required under most of the closed-shop agreements and those employees who are hired through other procedures must join the union before they start to work.

(2) Workers employed under a union-shop agreement need not be union members when hired, but they must join the union within a specified time, usually 30 to 60 days, and remain members during the period of employment. When the union-shop agreements specify that union members shall be given preference in hiring or that the hiring shall be done through the union, the effect is very much the same as the closed-shop agreement. Union shop clauses with preferential hiring have been combined with closed shop clauses in the categories shown in table E–2. In some cases, the union shop is modified so that those who were employed before the union shop was established are not required to become union members.

(3) Maintenance of membership, as a general rule, requires that all employees who are members of the union a specified time after the agreement is signed and all who later join the union must remain members in good standing for the duration of the agreement. Following the pattern of the maintenance-of-membership clause established by the National War Labor Board, most of the agreements with this type of union-security clause provide for a 15-day period during which members may withdraw from the union if they do not wish to remain members during the life of the agreement.

(4) Under preferential hiring no union membership is required but union members must be hired, if available. When the union cannot supply workers, the employer may hire nonmembers and they are not required to join the union as a condition of employment.

(5) Sole bargaining exists under some agreements which have no requirement for union membership or for hiring through the union. The union is the sole bargaining agent for all employees and negotiates the agreement covering all workers in the bargaining unit whether they are members of the union or not.

(6) During 1946, a few agreements covering workers employed by large companies, which had specified maintenance of membership in 1945, were modified to provide sole bargaining with the check-off of union dues for all union members, as a condition of employment.

(7) A few agreements stipulate that the union shall act as bargaining agent for its members only, and the agreement does not cover other workers.

In the preparation of the report on the extent of collective bargaining and union recognition, the total number of workers under union agreements is estimated from all available sources and classified by industry.

Figures on employment issued by the Bureau of Labor Statistics, the Bureau of Agricultural Economics, and the Bureau of the Census are used as a basis for estimating the potential number of workers subject to union agreements. The potential coverage (i.e., the number eligible for union-agreement coverage) excludes all self-employed, domestic workers, agricultural wage earners on farms employing fewer than 6 persons, and Federal and State government employees, teachers, and elected and appointed officials of local governments. The adjustments covering the proportions of potential workers under union agreement that were determined from the 1940 Census data have continued in use. When further information becomes available the necessary revisions will be made.

---

[3] These union security descriptions relate to types of collective bargaining provisions prevailing prior to enactment of the Labor Management Relations Act of 1947. They do not reflect changes in union security clauses necessitated by the 1947 act.

After having calculated the number of workers potentially under union agreement, those actually under such agreements, and the number under agreements providing certain types of union security, the ratios are calculated.

Changes in the proportion of workers under union agreement and in the prevalence of each type of union recognition are shown in table E-2 for the period 1942 through 1946. The series was started in 1941, when the calculations were made on a somewhat different basis. As the resultant figures are not strictly comparable with those for later years, they were omitted from table E-2.

Table E–2: Changes in union recognition, 1942–46

Item	1942	1943	1944	1945	1946
Eligible for union-agreement coverage:					
Number (in millions)	31	31	30.25	29	31.2
Percent under agreement	40	45	47	48	48
	Percentage distribution[1]				
Workers under agreements providing for—					
Closed shop	45	30	28	30	33
Union shop		20	18	15	17
Maintenance of membership	15	20	27	29	25
Preferential hiring	5	2	2	3	3
Other[2]	35	28	25	23	22
Total	100	100	100	100	100

[1] Percentages are not strictly comparable from year to year because of slight changes in the volume of employment during the period.

[2] No membership or hiring requirements are mentioned in these agreements, which have clauses specifying sole bargaining, maintenance of union dues, and bargaining for members only.

Work Stoppages

Statistical series on the number of work stoppages due to labor-management disputes, the workers involved, and the man-days of idleness caused by stoppages are compiled by the Bureau of Labor Statistics.

Work stoppages caused by labor-management disputes is the term used in recent years to describe the statistical series including strikes and lock-outs. However, use of this term does not represent a departure in coverage from that under the historical and more popular terminology of strikes and lock-outs. The definition of these terms as used by the Bureau is as follows:

> A strike is a temporary stoppage of work by a group of employees in order to express a grievance or to enforce a demand.
>
> A lock-out is a temporary withholding of work from a group of employees by an employer (or group of employers) in order to coerce them into accepting the employer's terms.[4]

Although the above definitions were first used in the middle 1930's the substance of the definitions has been used as a guide throughout the period covered by the series. The individual strike or lock-out—one concerted action—is the unit counted, irrespective of the number of unions or employers jointly involved in the controversy.

Stoppages involving fewer than 6 workers or lasting less than a full shift are excluded from the series. Such minor disputes usually have little appreciable effect on production, and the difficulties of obtaining adequate data make their inclusion in a statistical series impractical.

The figures on number of workers involved and number of man-days idle include data for all workers made idle in the establishments in which a strike or lock-out occurred. The data do not measure indirect or secondary idleness in other establishments which suspend or curtail operations owing to material or service shortages resulting from a work stoppage.

It is believed that the Bureau's figures on work stoppages, especially in late years, include substantially all strikes and lock-outs of any consequence. Initial notices are obtained from the press and from various Federal and State agencies dealing with labor-management disputes. The Bureau of Labor Statistics in 1947 obtained reports on strikes from over 250 daily newspapers and from many union and trade journals. Information is also obtained from the Federal Mediation and Conciliation Service and from several State labor agencies. Beginning with 1927, the Bureau has also obtained first-hand information through detailed questionnaires sent to the companies and unions involved. Previously, the number of workers involved was reported for only about two-thirds of the stoppages.

Estimates of the number of stoppages, number of workers involved, and number of man-days idle are given in table E–3 for 1916–47. Annual trends in work stoppages are shown from 1916 through 1947 and the monthly trends beginning in 1945. Also indicated are the average length of the stoppages each year (unweighted by the number of workers) expressed in terms of calendar days and in terms of the number of working days lost per worker involved.

The industry groups for which work-stoppage data are given in table E–4, covering 1935–47, are as defined by the Bureau of the Census for the year 1935 through 1941 and as defined by the Federal Government's Standard Industrial Classification Manual for 1942–47. Establishments involved in stoppages are classified by industry on the basis of their most important products or services in terms of number of employees producing them. In late years, the establishments were classified on the basis of their prewar products. An automobile plant, for example, which was converted to the production of aircraft during World War II was classified in the automobile industry throughout the period.

Work stoppages that occurred in 1935–47 are grouped in table E–5 according to major issues and by duration. Because many disputes involved varied and complex issues, the policy followed was to classify stoppages according to the major or most important issues. The duration of each stoppage was measured in terms of calendar days from the time the stoppage began until a settlement was reached. In a few instances, the date of termination, for statistical purposes, was determined by such factors as a substantial resumption of plant operations through use of nonstrikers, or the employer's liquidation of his business.

---

[4] United States Bureau of Labor Statistics, Bulletin No. 651, Strikes in the United States, 1880–1936 (p. 3).

Data by States (table E–6) include, except as noted below, all known stoppages in each State for the years 1935–47. Interstate stoppages are counted as separate stoppages in each State affected and the appropriate number of workers involved and man-days idle are allocated to the respective States. A few such interstate stoppages occurred which could not be so allocated owing to lack of information in the following years: 1935, 25 stoppages involving 16,300 workers; 1936, 2 stoppages involving 130; 1937, 5 involving 3,970; 1938, 5 involving 4,720 workers.

Work stoppages in 30 selected cities are shown in table E–7 for the prewar year 1939, the "defense" year, 1941, and the 3 most recent years, 1945, 1946, and 1947. Intercity stoppages affecting these cities were included, except as noted below, in the separate totals for each city affected, and the workers involved and man-days idle have been allocated to the respective cities. In 1946, it was impossible to obtain detailed information on 5 intercity stoppages with sufficient accuracy to permit allocations to the cities involved. The largest of these was the Nation-wide railroad strike in May. The others were smaller stoppages in the West Coast States. In 1947, also, it was impossible to allocate workers and man-days for 5 stoppages; three were construction workers' strikes in the Detroit, Mich., area, in the Lehigh Valley area near Allentown, Pa., and in northern New Jersey cities; one was a strike of retail grocery store clerks in the Los Angeles area; and one, a strike of bus drivers in several western States.

The extent to which each of the three major groups of unions (AFL, CIO, and independent or unaffiliated) were involved in stoppages from 1935 to 1947 is indicated in table E–8. The data do not include a few stoppages in which unions of different affiliation were jointly involved, those in which single-firm unions were involved, or those of unorganized workers.

Union involved in each case means the union directly participating in the stoppage.

Workers involved includes all workers made idle by the stoppage in the plant or establishment irrespective of union membership.

A chronological list of the stoppages involving 10,000 or more workers which occurred in the 13-year period 1935–47 appears in table E–9.

Table E–3: Extent of work stoppages, 1916–47

Period	Work stoppages beginning in period				Man-days idle (all stoppages)			Indexes (1935-39=100)

---

[1] Information on the number of workers involved in some strikes which occurred from 1916 to 1926 is not available. However, the missing information is for the smaller disputes, and it is believed that the totals here given are fairly accurate.

[2] "Total employed workers" as used here refers to all workers except those in occupations and professions in which there is little if any union organization or in which strikes rarely if ever occur. In most industries, it includes all wage and salary workers except those in executive, managerial, or high supervisory positions or those performing professional work the nature of which makes union organization or group action impracticable. It excludes all self-employed, domestic workers, agricultural wage workers on farms employing fewer than 6 persons, all Federal and State government employees, and the officials, both elected and appointed, in local governments.

[3] "Estimated working time" was computed for purposes of this table by multiplying the average number of employed workers each year by the number of days worked by most employees during the year.

TABLE E–4: Work stoppages in selected industry groups, 1935–47

Industry group	1935	1936	1937	1938	1939	1940	1941	1942	1943	1944	1945	1946	1947

---

[1] For the years 1935 to 1941 stoppages primarily over union organization matters but which also involved wage and hour issues were classified under "union organization."

[2] For the years 1935 to 1941 the stoppages primarily over inter- or intra-union matters (jurisdictional and rival union disputes) were classified under "other working conditions."

[3] Not available separately. Included above as "less than 1 week."

[4] Less than one-tenth of 1 percent.

Table E–6: Work stoppages by State, 1935–47

State and period	Work stoppages beginning in year			Man-days idle (all stoppages)	
	Number	Workers involved: Number	Workers involved: Percent of total for year	Number	Percent of total for year
Alabama:					
1935	59	38,300	3.4	1,120,000	7.3

*Stoppages in which single-firm unions, two or more rival unions, and no union were involved have been excluded from this table. Therefore, the percentages for any given year do not add to 100.

[1] Figures include strikes in which the 10 international unions suspended by the AFL in Sept. 1936 were involved. These unions were suspended for their activities in forming the Committee for Industrial Organization.

[2] During this period the United Mine Workers of America was affiliated with neither the AFL nor CIO.

TABLE E-9: Work stoppages involving 10,000 or more workers, 1935–47

Business and location	Beginning date	Approximate duration (calendar days)	Union involved	Approximate number of workers involved
1935:				
Shirt manufacturers, New York, New Jersey, Pennsylvania, and Connecticut.	Jan. 21	11	Amalgamated Clothing Workers (AFL)	15,000
Trucking companies, New York City	Jan. 28	1	Brotherhood of Teamsters (AFL)	20,000
Cotton dress companies, Chicago, Ill.	Feb. 20	50	International Ladies' Garment Workers' Union (AFL)	10,000
Dress manufacturers, New York, New Jersey, Pennsylvania, and Connecticut.	April 9	8	International Ladies' Garment Worker's Union (AFL)	17,000
Lumber industry, Washington and Oregon	May 6	104	Sawmill and Timber Workers (AFL)	32,000
General strike, Terre Haute, Ind.	July 22	2	General strike (AFL Unions)	26,000
Dress manufacturers, New York City	Sept. 3	9	International Ladies' Garment Workers' Union (AFL)	10,000
Bituminous-coal mines, 23 States	Sept. 23	6	United Mine Workers (AFL)	366,000
Bituminous-coal mines, Alabama	Sept. 23	56	United Mine Workers (AFL)	20,000
1936:				
Millinery companies, New York City	Feb. 4	7	United Hatters, Cap and Millinery Workers (AFL)	20,000
Goodyear Tire & Rubber Co., Akron, Ohio	Feb. 17	34	United Rubber Workers (AFL)	14,000
Realty owners, New York City	Mar. 1	15	Building Service Employees (AFL)	36,000
Barber shops, New York City	Apr. 27	71	The Journeymen Barbers (AFL)	20,000
Goodyear Tire & Rubber Co., Akron, Ohio	June 10	1	United Rubber Workers (AFL)	12,000
Painting contractors, New York City	Aug. 27	9	Brotherhood of Painters (AFL)	10,000
Maritime industry, Pacific Coast	Oct. 30	98	International Longshoremen's Association (AFL), Marine Engineers' Beneficial Association (Ind.), Masters, Mates and Pilots (AFL), Marine Firemen, Oilers, Watertenders and Wipers Association (Ind.), Marine Cooks and Stewards (AFL), American Radio Telegraphists Association (Ind.), and Sailors Union of the Pacific (Ind.).	37,000
Maritime industry, Atlantic and Gulf Coasts	Nov. 1	85	International Seamen's Union (AFL)	20,000
1937:				
General Motors Corp., 6 States	Jan. 1	42	United Automobile Workers (CIO)	48,000
B. F. Goodrich Co., Akron, Ohio	Jan. 28	3	United Rubber Workers (CIO)	10,000
Shirt manufacturers, New York, New Jersey, Connecticut, and Pennsylvania.	Feb. 16	10	Amalgamated Clothing Workers (CIO)	12,000
Shoe manufacturers, Massachusetts	Feb. 23	9	United Shoe and Leather Workers (CIO)	11,500
Firestone Tire & Rubber Co., Akron, Ohio	Mar. 3	59	United Rubber Workers (CIO)	10,500
Chrysler Corp., Detroit, Mich.	Mar. 8	30	United Automobile Workers (CIO)	63,000
Hudson Motor Car Co., Detroit, Mich.	Mar. 8	34	United Automobile Workers (CIO)	10,000
General Motors Corp., Flint, Mich.	Mar. 8	1	United Automobile Workers (CIO)	13,000
General Motors Corp., Flint, Mich.	Apr. 1	3	United Automobile Workers (CIO)	14,000
Bituminous-coal mines, Alabama	Apr. 2	43	United Mine Workers (CIO)	15,000
Caterpillar Tractor Co., Peoria, Ill.	Apr. 6	3	Amalgamated Association of Iron, Steel and Tin Workers (CIO-SWOC).	11,000
Anthracite mines, Pennsylvania	May 3	23	United Mine Workers (CIO)	15,000
Jones and Laughlin Steel Corp., Aliquippa and Pittsburgh, Pa.	May 12	3	Steel Workers Organizing Committee (CIO)	25,000
Independent steel companies, Republic, Youngstown Sheet & Tube, Inland, and Bethlehem.	May 26	64	Steel Workers Organizing Committee (CIO)	92,000
General strike, Lansing, Mich.	June 7	1	United Automobile Workers (CIO)	15,000
General Motors Corp., Detroit, Mich.	June 8	8	United Automobile Workers (CIO)	11,000
Shipyards, New York and New Jersey	June 11	69	Industrial Union of Marine and Shipbuilding Workers (CIO)	15,000
Captive coal mines, Pennsylvania and West Virginia	June 14	45	United Mine Workers (CIO)	10,000
Trucking companies, Philadelphia, Pa.	July 2	2	Brotherhood of Teamsters (AFL)	20,000
Cloak manufacturers, New York and New Jersey	July 8	5	International Ladies' Garment Workers' Union (CIO)	12,000
Bituminous-coal mines, Illinois	July 31	28	Progressive Mine Workers (Ind.)	16,000
Chrysler Corp., Detroit, Mich.	Aug. 4	4	United Automobile Workers (CIO) and Independent Association of Chrysler Employees (Ind.).	10,000
Silk manufacturers, New York, New Jersey, and Pennsylvania	Aug. 9	23	Textile Workers Organizing Committee (CIO)	31,000
Painting contractors, New York City	Aug. 26	20	Brotherhood of Painters (AFL)	13,000
Hudson Motor Car Co., Detroit, Mich.	Nov. 9	1	United Automobile Workers (CIO)	10,500
Goodyear Tire & Rubber Co., Akron, Ohio	Nov. 19	3	United Rubber Workers (CIO)	13,500
1938:				
Hosiery mills, New York, New Jersey, and Pennsylvania	Feb. 28	4	American Federation of Hosiery Workers (CIO)	21,000
Trucking companies, New Jersey and New York City	Sept. 15	19	Brotherhood of Teamsters (AFL)	18,000
1939:				
Chrysler Corp., Detroit, Mich.	Feb. 22	2	United Automobile Workers (CIO)	10,000
Bituminous-coal mines, 23 States	Apr. 1	48	United Mine Workers (CIO)	330,000
Bituminous-coal mines, Harlan County, Ky.	May 19	62	United Mine Workers (CIO)	14,000
Briggs Manufacturing Co., Detroit, Mich.	May 22	17	United Automobile Workers (CIO)	15,000
W. P. A. projects, 38 States	July 5	16	Workers Alliance (Ind.)	123,000
Building and construction industry, Philadelphia, Pa.	Aug. 29	10	Philadelphia Building Trades Council and Plumbers and Steamfitters (AFL).	15,000
Chrysler Corp., Detroit, Mich.	Oct. 6	55	United Automobile Workers (CIO)	50,000
Cotton growers, California	Oct. 9	53	Cannery, Agricultural, Packing and Allied Workers (CIO)	15,000
1940:				
Clothing industry, New York	July 11	2	International Ladies' Garment Workers' Union (AFL)	15,000
Painting contractors, New York, Connecticut, and District of Columbia.	Aug. 26	32	Brotherhood of Painters (AFL)	15,000
Building and construction industry, St. Louis, Mo.	Oct. 25	4	St. Louis Building and Construction Trades Council (AFL)	15,000
Lumber companies, Oregon and Washington	Dec. 2	15	Lumber and Sawmill Workers (AFL)	12,000
1941:				
International Harvester Co., Illinois, and Indiana	Jan. 17	73	Farm Equipment Organizing Committee (CIO)	16,000
Bethlehem Steel Corp., Lackawanna, N. Y.	Feb. 27	2	Steel Workers Organizing Committee (CIO)	12,000
Bethlehem Steel Corp., Bethlehem, Pa.	Mar. 24	4	Steel Workers Organizing Committee (CIO)	10,000
Bethlehem Steel Corp., Johnstown, Pa.	Mar. 28	3	Steel Workers Organizing Committee (CIO)	10,000
Bituminous-coal mines, Illinois	Apr. 1	15	Progressive Mine Workers (AFL)	15,000
Bituminous-coal mines, Alabama, Illinois, and Iowa	Apr. 1	44	United Mine Workers (CIO)	49,000
Bituminous-coal mines, 14 States	Apr. 1	30	United Mine Workers (CIO)	269,000
Ford Motor Co., Dearborn, Mich.	Apr. 1	11	United Automobile Workers (CIO)	85,000
Lumber industry, Washington	May 9	37	International Woodworkers (CIO)	12,000

Allis-Chalmers, 7 plants in 6 States	Mar. 14	(11)	United Automobile Workers (CIO), United Farm Equipment and Metal Workers (CIO), United Electrical Workers (CIO), and CIO Industrial Union, 1424.	25,000
Bituminous-coal mines, industry-wide	Apr. 1	59	United Mine Workers (AFL after Jan. 1946)	340,000
Port of Philadelphia	Apr. 5	6	CIO and AFL Unions in support of the United Harbor Workers (District 50, United Mine Workers AFL).	18,000
Briggs Manufacturing Co., Detroit, Mich.	May 3	1	United Automobile Workers (CIO)	11,000
Railroad industry, Nation-wide	May 23	2	Brotherhood of Locomotive Engineers and Brotherhood of Railroad Trainmen (Ind.).	350,000
City of Rochester, N. Y.	May 28	1	AFL and CIO Unions—general sympathy strike	20,000
Anthracite mines, Pennsylvania	May 31	8	United Mine Workers (AFL)	75,000
Association of General Contractors of America, Cincinnati, Ohio	June 3	2	Hod Carriers, Building and Common Laborers (AFL)	10,000
Railway Express Co., New York City and Hudson County, N. J.	June 27	5	Brotherhood of Railway and Steamship Clerks, Freight Handlers, Express and Station Employees (AFL).	12,000
Motion picture studios, Los Angeles (Hollywood), Calif.	July 1	2	Conference of Studio unions (comprising AFL craft affiliates)	14,000
New York City and other Atlantic ports	July 10	4	Seafarers' International Union (AFL) and its affiliated Sailors Union of the Pacific (Supported by other AFL unions). National Maritime Union (CIO).	11,500
Waterfront Employers' Association San Francisco; Long Beach, and Los Angeles, Calif.	July 31	(12)	International Longshoremen's and Warehousemen's Union (CIO)	12,000
Building and construction industry, Buffalo, N. Y.	Aug. 12	11	Allied Building Trades Council (AFL)	18,000
General Motors Corp.—Fisher Body Plant, Truck and Coach Division, Pontiac Motor Division.	Aug. 14	1	United Automobile Workers (CIO)	11,000
Commercial and industrial construction, Cuyahoga, Geauga, and Lake Counties, Ohio.	Aug. 29	2	Building Trades (AFL)	24,000
Trucking companies, New York City area and New Jersey	Sept. 1	(13)	Brotherhood of Teamsters (AFL)	31,000
Maritime industry, unlicensed personnel—Atlantic, Gulf, and Pacific Coast ports.	Sept. 5	17	Sealarers' International Union (AFL) and its affiliate, Sailors Union of the Pacific, National Maritime Union (CIO), Marine Cooks and Stewards (CIO), and Marine Firemen, Oilers, Watertenders and Wipers Association (Ind.), supported by other AFL Unions.	132,000
Hudsnn Motor Car Co., Detroit, Mich.	Sept. 11	1	United Automobile Workers (CIO)	12,000
Maritime industry, licensed personnel—Atlantic, Gulf, and Pacific Coast ports; longshoremen on Pacific Coast.	Oct. 1	(14)	Marine Engineers Beneficial Association (CIO), Masters, Mates and Pilots (AFL), International Longshoremen's and Warehousemen's Union (CIO).	142,000
Transcontinental & Western Air, Inc. (Trans World Airline)	Oct. 21	26	Air Line Pilots Association (AFL)	13,000
Bituminous-coal mines, industry-wide[15]	Nov. 21	17	United Mine Workers (AFL)	[15]335,000
General strike, Oakland, Calif.	Dec. 3	2	Retail Clerks' Intl. Association (AFL) in original dispute. AFL unions participated in general sympathy strike.	50,000

---

[1] Intermittent idleness for total of 18 days during September, October, and November.

[2] Average per worker 20 days. Includes intermittent stoppages April through November.

[3] Average per worker 21 days. Includes intermittent stoppages May through November.

[4] Stoppage began Aug. 17; however, majority of workers did not become idle until September.

[5] About 45,000 workers were idle by Sept. 30. The remainder became idle during October.

[6] Settlements reached with a few companies prior to December 1945. Majority of agreements signed by late December, with most of the remaining settlements occurring at some time in the following 3 months.

[7] Agreement reached on Mar. 13, 1946; ratification by local unions, together with plant production problems, delayed reopening of most plants until late in the month. A few plants continued idle into April.

[8] General Motors Corp. (Electrical Division) settled on Feb. 9, General Electric Co. on March 14, and Westinghouse Electric and Manufacturing Co. on May 10.

[9] Settlement on Feb. 15, 1946, with U.S. Steel Corp., followed by agreements with other large basic steel companies within 4 days, resulted in the return to work of approximately 450,000 employees. Virtually all the remaining 300,000 workers went back to their jobs at various dates during the next 2 months as additional settlements were reached.

[10] Chase Brass Co. settled on April 6 and American Brass Co. on May 19.

[11] Duration of stoppages at various plants as follows: LaPorte, Ind., Mar. 14-Oct. 12; Norwood, Ohio, Mar. 19-Sept. 28; Pittsburgh, Pa., Mar. 22-Sept. 16; Springfield, Ill., Apr. 16-Sept. 18; Hyde Park (Boston), Mass., Apr. 30-Dec. 8; LaCrosse, Wis., Apr. 30-Oct. 24; West Allis, Wis., Apr. 30, 1946-Mar. 23, 1947.

[12] Majority of employees resumed work Aug. 1; some idleness continued through Aug. 1 in Los Angeles area.

[13] Some settlements were reached on Sept. 17. Virtually all other employers settled in the following 6 weeks.

[14] MEBA and MMP on East and Gulf Coasts signed agreements on Oct. 22 and Oct. 26, respectively. West Coast stoppage continued until Nov. 23.

[15] This figure does not include some 7,500 anthracite miners who were idle for 2 days during this period following an erroneous report that their president had been jailed.

Table E–9: Work stoppages involving 10,000 or more workers, 1935–47—Continued

Business and location	Beginning date	Approximate duration (calendar days)	Union(s) involved	Approximate number of workers involved
1947:				
Hudson Motor Car Company, Detroit, Mich.	Jan. 27	2	United Automobile Workers (CIO)	14,000
Telephone industry, Nation-wide	Apr. 7	[16]44	National Federation of Telephone Workers (Ind.)	370,000
Statewide demonstration, Iowa	Apr. 21	1	Various unions (AFL & CIO)	100,000
Inland Steel Co., East Chicago, Ind. and Chicago Heights, Ill.	May 1	7	United Steelworkers (CIO)	14,000
Construction industry, Detroit, Mich. area	May 1	[17]47	Building trades unions (AFL)	19,000
Construction industry, Lehigh Valley area, Pennsylvania	May 1	[18]38	Building trades unions (AFL)	10,000
Metal trades industries, Washington State	May 16	4	Metal Trades Council (AFL) and International Association of Machinists (Ind.)	10,000
Remington Rand, Inc., New York and Michigan	May 26	[19]70	International Association of Machinists (Ind.) and United Electrical, Radio, and Machine Workers (CIO) beginning June 18	15,000
Construction industry, Philadelphia, Pa. area	June 5	13	Building trades unions (AFL)	15,000
Bituminous-coal mines, Indiana and southwestern Pennsylvania	June 6	(20)	United Mine Workers (AFL)	18,000
Hudson Motor Car Co., Detroit, Mich.	June 11	2	United Automobile Workers (CIO)	16,000
Bituminous-coal mines, industry-wide	June 23	(21)	United Mine Workers (AFL).	343,000
Shipyards, Atlantic and Gulf Coasts and San Pedro, Calif.	June 26	(22)	International Union of Marine and Shipbuilding Workers (CIO)	50,000
Union Railroad and Carnegie Illinois Steel Corp., Pittsburgh, Pa. area.	Sept. 5	9	Railroad Trainmen (Ind.) and Locomotive Engineers (Ind.) (Ind.)	[23]23,000
Railway Express Agency, Inc., New York City and nearby New Jersey.	Sept. 19	25	Teamsters (AFL)	10,000

---

[16] Major portion of strike ended by May 20, some companies settled earlier and several not until the last week in May.

[17] Settlements involving substantial numbers of workers were reached May 29, June 16, and July 14.

[18] Stoppage terminated by June 7 for all trades except electricians and roofers who remained out until June 24.

[19] Electrical workers settled July 28, machinists August 3.

[20] Most workers idle not more than 3 working days.

[21] Between June 23-27 over 200,000 stopped work allegedly in protest against passage of the Labor Management Relations Act by Congress. June 28-July 7 was the scheduled industry-wide vacation period. On June 30, the mines, operated by the Government since May 1946, were returned to private control. After the scheduled vacation, most miners were idle from July 8-11 until contracts with operators were signed and ratified.

[22] About 25,000 stopped work June 26; an additional 25,000 went out July 1. Some companies settled during July, August, and September. Agreement covering most Bethlehem Steel yards was reached by November 7. The last plants to settle were the Patapsco Scrap Corp. (a subsidiary of Bethlehem Steel) at Fairfield, Md. (Nov. 16), and the San Pedro, Calif., plant of Bethlehem Steel (Dec. 24).

[23] About 1,900 employees of the Union Railroad (a subsidiary of U. S. Steel Corp. servicing steel plants) were involved in the dispute and about 21,000 steel workers in closely integrated operations were made idle.

Conciliation Service Cases

The Conciliation Service of the United States Department of Labor assisted in the settlement of labor-management disputes and otherwise aided employers and unions in matters pertaining to labor relations problems. Requests for such service were usually made by one or both parties to a labor dispute, although the Service could enter cases on its own initiative where the public interest required it. Cases closed were classified and tabulated in categories which are defined as follows:

Work stoppage—a strike or lock-out.[1]

Threatened stoppage—a situation in which a definite strike date has been announced or a 30-day strike notice has been filed by a union pursuant to the War Labor Disputes Act.

Controversy — a dispute which has not reached the stage of a work stoppage or threatened stoppage.

Arbitration—arbitration decisions rendered by arbitrators appointed by the Conciliation Service upon request of both parties to a dispute. These arbitrators were appointed to render final and binding awards which the parties had agreed to accept in advance of the award.

Technical activities—the conducting of surveys upon the joint request of both parties to a dispute and the giving of advice to companies and unions on such technical matters as wage incentive plans, time studies, and job evaluations.

Miscellaneous special services—services provided upon request—such as the furnishing of labor relations information, consultation with labor and management representatives on specific problems, and addresses to interested groups concerning the Conciliation Service, labor problems, and related subjects.

The total number of situations dealt with and workers involved are shown in table E–10 by type of case for the fiscal years 1940–41 through 1946–47.

---

[1] The total number of work stoppages which the Conciliation Service assisted in settling is not comparable with the total number of work stoppages reported by the Bureau of Labor Statistics in table E–3. The Bureau of Labor Statistics total tended to be larger because it included stoppages in which the assistance of the Conciliation Service was not utilized.

TABLE E-10: Cases closed by the United States Conciliation Service, fiscal years 1940-41 through 1946-47

Type of case	1940—41		1941—42		1942—43		1943—44		1944—45		1945—46		1946—47

National Labor Relations Board Cases

The trend in the number of cases filed with and handled by the National Labor Relations Board in the fiscal years 1935-36 through 1946-47 is given in table E-11.

Recourse to formal action in the settlement of representation and unfair labor practice cases means that the Board held formal hearings and issued formal decisions in cases in which other means of settlement were ineffective.

TABLE E–11: Disposition of cases by the National Labor Relations Board, fiscal years 1935–36 through 1946–47

Cases	Fiscal year—											
	1935-36	1936-37	1937-38	1938-39	1939-40	1940-41	1941-42	1942-43	1943-44	1944-45	1945-46	1946-47

Section F: Productivity and Unit Labor Cost

Productivity, as the term is used here, refers to output in physical units per man-hour of work. The indexes of output per man-hour were obtained by dividing indexes of production by indexes of man-hours. Unit labor cost is the wage payment per physical unit of output. The indexes of unit labor cost were derived by division of pay-roll indexes by production indexes.

Data on productivity and unit labor cost which are published by the Bureau of Labor Statistics are obtained largely from Government sources.

Productivity is a measure of the relationship between the volume of goods produced and one factor of input—labor time. The data do not measure the specific contribution of labor or of capital or of any other single factor of production. The output per man-hour indexes also do not reflect increased efficiency or lowered costs resulting from such long-time trends as more economical use of fuel and materials or more efficient integration of industries. Changes in the ratio between output and man-hours of work show the joint effect of a large number of separate, though interrelated, influences. The long-term upward trend of output per man-hour is due mainly to technical improvements in industrial organization and processes. At any time, however, output per man-hour also depends on such factors as the rate of operations, the relative contributions to production by plants at different levels of efficiency, the types of resources and materials available, the flow of materials, the skill and effort of the work force, the efficiency of management, and the state of labor relations.

Figures for the years after 1939 have been influenced by the effect of wartime and reconversion conditions on these factors and also on the products of many industries. The reports concerning a considerable number of the industries for which indexes were compiled through 1939 had to be discontinued at least temporarily, both because of the absence of Census data after 1939 and because of the change in the nature of the products manufactured during the war years.

The manufacturing industries for which series are continuous, therefore, are only a part of the total and should not be taken together to represent manufacturing as a whole nor should the figures be averaged to represent all manufacturing. The figures are therefore applicable only to the individual industries which they represent and any generalizations concerning productivity trends should be interpreted in the light of the changes which have taken place since 1939. Furthermore, adjustments may be necessary in individual series as additional data, especially from the 1947 Census of Manufactures, become available.

The unit labor cost index relates wages, a money value measure, to production, a physical volume measurement. To convert both these elements—wages and production—into money values would involve comparison of pay-roll indexes with value of production as reported in the Census of Manufactures. The indexes of unit labor cost give no indication of changes in the relative importance of labor cost to other production costs. However, data are not available to make these comparisons on a current basis. Moreover, the indexes of unit labor cost should be interpreted in relation to other costs and to profits, since in a time of rising prices these relationships are especially significant.

Output per man-hour (output per worker in agriculture) and unit labor cost for broad segments of the economy—manufacturing, mining, agriculture, railroads, electric light and power, telephone, and telegraph—are shown in index form in table F–1 for selected periods between 1909 and 1947. Details of construction of these indexes are explained in footnotes. As the production pattern changed markedly when the United States began its World War II production program, it is not possible to measure the over-all changes in manufacturing efficiency from peace to war. Consequently the indexes for the all-manufacturing group are not extended beyond 1939. Indexes for individual manufacturing industries are given in table F–2; those for mining in table F–3; and in table F–4 the output per worker in agriculture is given by farming areas.

TABLE F–1: Indexes of output per man-hour (output per worker in agriculture) and unit labor cost for selected industries, selected years 1909–47

---

[1] See footnote 1, table F–2.

[2] See footnote 1, table F–3.

[3] See footnote 1, table F–4.

[4] The indexes refer to class I steam line-haul railroads. For the 1935–47 segment, the oduction index represents aggregate passenger-miles and freight ton-miles, each tegory being weighted by respective average unit revenues in 1939. The man-hours lex represents the total of straight time actually worked, all overtime paid for, and nstructive-allowance hours of train and engine employees. The index of pay rolls ers to total compensation of hourly basis employees including that represented by called "time paid for but not worked." All data were obtained from published reports the Interstate Commerce Commission. The 1916–34 segments are based on slightly ferent indexes published by the Bureau of Labor Statistics in 1937.

[5] The series refer to privately owned electric utilities. For Census years through 1937, y are based on data from the quinquennial Census of Electrical Industries. The luction index represents kilowatt-hour sales to ultimate consumers in Census years; etricity generated by privately owned utilities as reported by the Federal Power mmission, was used in intervening years. All wage and salary employees, except main cutives and employees of appliance sales departments, are included in the employnt index. Estimates for certain years between 1917 and 1927 were based on employnt in private electric companies published by the Edison Electric Institute. For the riod since 1929, employment is represented by the Bureau of Labor Statistics index the electric light and power industry. The index of man-hours was derived from the ployment index and average weekly hours of wage earners, from a study published by the National Research Project of the Work Projects Administration for the period 1917–31 and from the Bureau of Labor Statistics for later years. The Bureau of Labor Statistics index of pay rolls was used for the period beginning with 1929.

[6] The indexes are based on Federal Communications Commission data and refer to class A telephone carriers. The production index is based on the number of originating local and toll calls, weighted by average revenue per local call and per toll call in 1939. The index of man-hours was derived from the employment measure and a series for average weekly hours. The weekly hour series was obtained from Bureau of Labor Statistics data for the telephone and telegraph industries combined for 1935–39 and for the telephone industry alone from 1939. The pay-roll index was computed from Federal Communications Commission statistics for total annual compensation to all employees.

[7] The indexes are based on Federal Communications Commission data for the principal wire-telegraph and ocean-cable carriers. The production index is based on Federal Communications Commission series for (1) domestic messages, land-line companies; (2) foreign messages, land-line companies; (3) domestic messages, ocean-cable companies; and (4) foreign messages, ocean-cable. Each series was weighted by the corresponding unit revenue in 1939. As satisfactory data on average weekly hours are not available before 1943, an index of output per man-hour is not presented. The employment index is based on averages of the number of employees of all classes in service at the end of June and at the end of December (June and October for 1944) adjusted to represent annual averages. The pay-roll index was computed from Federal Communications Commission data for total annual compensation to all employees.

TABLE F–2: Indexes of output per man-hour and unit labor cost in selected manufacturing industries, 1919–47

[1939=100]

Period	All manufacturing[1]		Beet-sugar refining		Bread and other bakery products		Cane-sugar refining		Canning and preserving group		Cement

---

[1] The production indexes for 1909, 1914, and the odd-numbered years in the 1919-39 period are from Employment in Manufacturing, 1899-1939, by Solomon Fabricant (National Bureau of Economic Research). The indexes for the years 1920-38 were completed by using the Federal Reserve index for manufactures. The indexes of employment and pay rolls are based on Bureau of Labor Statistics and Bureau of the Census statistics. The index of man-hours was derived from an employment index and a series for average weekly hours including Bureau of Labor Statistics figures for 1909, 1914, 1919, and 1923-39 and estimates for 1920-22, based on Bureau of Labor Statistics data for average weekly earnings and data for average hourly earnings as shown in Employment, Hours, and Earnings, in Prosperity and Depression, United States, 1920-22, by W. I. King.

[2] For the period beginning with 1940, the Bureau of Labor Statistics is reviewing its indexes of output per man-hour and unit labor cost for selected manufacturing industries. The indexes presented here represent tentative revisions made in May 1947 and replace those published in the mimeographed report, Productivity and Unit Labor Cost in Selected Manufacturing Industries, 1939-45, May 1946. The indexes are compiled as broad measures of general trend. Because of the wide interest in these measures, detailed statements showing the basic data and describing the procedures used in the computation of the revised indexes have been prepared and sent to interested persons for comment and suggestions prior to publication in final form. The revised series (including any further revisions deemed necessary) extended through 1947, will be published at a later date together with current data for those industries for which no indexes are shown after 1939.

[3] New series; covers cigarettes, chewing and smoking tobacco, and snuff combined.

TABLE F-3: Indexes of output per man-hour and unit labor cost in selected mining industries, 1935–47

[1939=100]

[1] The indexes of output per man-hour for 1935-47 cover six of the principal mining ndustries as shown. Crude petroleum, natural gas, and natural gasoline, for which no nit labor costs are available, are excluded from the index of unit labor cost. The index f production is an average of the separate production indexes weighted with current-ear man-hours; the indexes of man-hours and pay rolls are based on Bureau of Labor tatistics data. The series for 1915-34 is based on an index covering almost all mining ndustries, prepared by the WPA National Research Project, Production, Employment, nd Productivity in the Mineral Extractive Industries, 1880-1938. The indexes of output per man-hour and unit labor cost include tentative revisions made in August 1947 The revisions result from tentative adjustments in the Bureau's employment series, t data published by the Bureau of Employment Security of the Federal Security Agency

[2] Five mining industries; excludes crude petroleum, natural gas, and natural gasoline for which no unit labor costs are available.

[3] Pending further review, the tentative revisions for crude petroleum, natural gas, and natural gasoline for the years 1940-47 were not considered sufficiently reliable for publication. Data for this industry were considered satisfactory for inclusion in the combined indexes for the six principal mining industries.

TABLE F-4: Indexes of output per worker in agriculture, total and 11 farming areas, 1935–47[1]

[1939=100]

Period	United States[2]	Corn area	Eastern dairy area	Western dairy area	Eastern cotton area	Delta cotton area	Western cotton area	Small grain area	Middle eastern area	Range area	Northwestern area	California

1947	116.9	104.1	113.5	116.8	120.4	84.4	120.6	134.5	124.9	127.6	111.1	115.3

[1] Indexes are shown for the United States as a whole and for 11 farming areas. Six States are not included in these areas—Maine, Rhode Island, New Jersey, Delaware, Florida, and Missouri. The States included in each area are as follows: **Corn area**—Illinois, Indiana, Iowa, Ohio; **Eastern dairy area**—Connecticut, Massachusetts, New Hampshire, New York, Pennsylvania, Vermont; **Western dairy area**—Michigan, Minnesota, Wisconsin; **Eastern cotton area**—Alabama, Georgia, South Carolina; **Delta cotton area**—Arkansas, Louisiana, Mississippi; **Western cotton area**—Oklahoma, Texas; **Small grain area**—Kansas, Montana, Nebraska, North Dakota, South Dakota; **Middle Eastern area**—Kentucky, Maryland, North Carolina, Tennessee, Virginia, West Virginia; **Range area**—Arizona, Colorado, Nevada, New Mexico, Utah, Wyoming; **Northwestern area**—Idaho, Oregon, Washington, California.

[2] The series for 1909-34 was derived from indexes prepared by the WPA National Research Project and shown in the reports, Trends in Size and Production of the Aggregate Farm Enterprise, 1909–36, and Trends in Employment in Agriculture, 1909-36. The series for 1935-47 is based on Bureau of Agricultural Economics data. The employment series includes all persons, regardless of age, engaged in farm work for 2 or more days a week, proprietors, family workers, and hired workers. The production index was derived from statistics for gross farm output of 73 products combined with weights representing the estimated labor requirements per unit of gross output.

Section G: Work Injuries

Work-injury data regularly compiled by the Bureau of Labor Statistics include (1) annual estimates of the total volume of work injuries n each major manufacturing and nonmanufac-uring classification, (2) current injury frequency rates for the primary manufacturing ndustry classifications, (3) annual injury frequency and severity rates for manufacturing and nonmanufacturing industry classifications, and (4) accident cause statistics for selected ndustry classifications.

Injury frequency rate means the average number of disabling injuries for each million employee-hours worked.

All available data relating to work injuries are utilized in the preparation of the national estimates that are made annually. Inasmuch as there is no uniform requirement concerning he reporting of work injuries, the information available is incomplete and for some groups is extremely limited. In general, accident reports are received by Federal agencies such as the Bureau of Labor Statistics, the Bureau of Mines, the Interstate Commerce Commission, and by the various State workmen's compensation bureaus. To compile the country-wide estimates, the tabulated injury totals prepared by these agencies are related to the appropriate segments of the national employment, and the national injury estimates are computed by direct expansion to represent the probable volume of injuries in the total working population.

At the end of each quarter, about 14,000 manufacturing establishments are requested to supply information for each month of the quarter regarding the number of workers employed, the number of employee-hours worked, the number of disabling work injuries experienced by their employees, and a break-down indicating the resulting type of disability as known at the time of preparing the report. Generally, about 11,000 voluntary reports are received from employers in time for the quarterly tabulations.

All of these data are incorporated into the more comprehensive annual surveys.

At the end of each year, voluntary annual summary reports are solicited from an additional mailing list of about 50,000 employers. Some 25,000 manufacturing establishments and about 15,000 nonmanufacturing establishments usually report in this survey. Such reports are classified according to the principal product or operation of the respective establishments, and the reported data are totaled by industry classification. From these totals the injury frequency and severity rates are computed following, with one exception, the procedures specified in the American Standard Method of Compiling Industrial Injury Rates. The single exception is that the full-time charges for each permanent-partial disability are used rather than the percentage charges as permitted under the Standard Method. The computed rates for the various industry classifications are then weighted according to the total estimated employment in the classification and are combined in the computation of weighted rates for the major industry groups.

Special surveys are made within selected industries to obtain greater coverage and greater detail than is possible in the regular surveys, and to determine the prevailing causes of the accidents which produce work injuries. An attempt is made to obtain a report from every employer in the industry. From these reports, frequency and severity rates are computed for each type of operation commonly found in the industry, for plants in various size groups, and for plants in various geographic areas.

In addition, representatives of the Bureau of Labor Statistics visit a number of establishments in the selected industry and ask permission to review their original accident records. If permission is given, the Bureau representative examines the records and for each recorded accident prepares a transcript indicating (1) how, when, and where the accident occurred; (2) what unsafe conditions and/or unsafe acts contributed to the accident; and (3) what type of injury resulted. These data are then analyzed and tabulated according to the provisions of the American Recommended Practice for Compiling Industrial Accident Causes as approved by the American Standards Association.

The estimates of time lost owing to disabling work injuries shown in table G–1 for 1940–47 include actual man-days lost in the year the injury occurred and also future economic losses.

The estimated number of work injuries classified by the extent of disability are shown in table G–2, by major manufacturing and nonmanufacturing industry groups, for the years 1936–47. In table G–3 the injury frequency rates and indexes of injury frequency rates, according to the extent of disability in manufacturing industries, are given for 1926–47.

Bureau of Labor Statistics records of work-injury frequency rates are shown in table G–4 for 87 individual industries for the period 1941–47. The number of industry groups for which data are tabulated separately is currently considerably greater. However, changes in industrial classifications prevent the same historical presentation for other individual series.

Man-days lost in the year of injury are the actual number of days in that year during which the employee was unable to work because of this injury.

Economic loss includes both actual days lost in the year of injury and allowances for subsequent losses of working time and working ability owing to the injury.

TABLE G–1: Estimated number of work injuries and resulting time lost, 1940–47

Period	Number of disabling injuries	Man-days lost	
		In year of injury	In subsequent years (economic loss)
1940......	1,889,700	41,912,000	191,928,000
1941......	2,180,200	42,083,000	209,000,000
1942......	2,267,700	53,000,000	210,000,000
1943......	2,414,000	56,800,000	217,200,000
1944......	2,230,400	43,614,400	179,329,600
1945......	2,019,800	45,600,000	185,664,000
1946......	2,056,000	42,750,000	187,250,000
1947......	2,059,000	44,700,000	189,000,000

TABLE G–2: Estimated number of work injuries (major manufacturing and nonmanufacturing industry groups), by extent of disability, 1936–47

Industry group and type of disability	1936	1937	1938	1939	1940	1941	1942	1943	1944	1945	1946	1947
All industry groups: Total	1,407,200	1,838,000	1,375,600	1,603,500	1,889,700	2,180,200	2,267,700	2,414,000	2,230,400	2,020,300	2,056,000	2,059,000
Fatalities	16,000	19,600	16,400	16,400	18,100	19,200	18,100	18,400	15,900	16,500	16,500	17,000

[1] Permanent-total included in permanent-partial.
[2] Permanent-total included in fatalities.
[3] Based on fragmentary data.
[4] Based largely on Bureau of Mines data.
[5] Based on small sample studies.
[6] Based on comprehensive surveys.
[7] Less than 50.
[8] Based on Interstate Commerce Commission data.

TABLE G–3: Work-injury frequency rates and indexes of work-injury frequency rates (manufacturing), by extent of disability, 1926–47[1]

Period	Injury frequency rates[2]	Index of frequency rates (1926 = 100)[3]			
		All injuries	Death and permanent-total	Permanent-partial	Temporary-total
1926......	24.2	100.0	100.0	100.0	100.0
1927......	22.6	93.6	107.1	96.3	93.3
1928......	22.5	93.2	107.1	104.6	92.5
1929......	24.0	99.2	92.9	109.2	98.7
1930......	23.1	95.5	107.1	111.0	94.6
1931......	18.9	78.0	92.9	102.8	76.5
1932......	19.6	80.9	107.1	113.8	78.9
1933......	19.3	91.8	85.7	110.1	90.8
1934......	20.2	93.6	107.1	128.4	91.6
1935......	17.9	88.1	92.9	121.1	86.2
1936......	16.6	85.7	85.7	114.7	84.1
1937......	17.8	85.8	85.7	122.0	83.7
1938......	15.1	71.7	71.4	78.9	68.1
1939......	14.9	73.4	71.4	80.7	73.9
1940......	15.3	75.3	71.4	84.8	75.6
1941......	18.1	85.8	80.3	93.7	86.3
1942......	19.9	93.5	70.7	83.4	94.1
1943......	20.0	94.4	70.7	83.4	95.0

1945......	18.6	81.9	62.8	72.3	83.0
1946......	19.9	84.3	60.1	77.9	85.3
1947......	18.8	78.4	51.7	70.1	79.3

[1] Prior to 1936 the coverage in the Bureau of Labor Statistics surveys was limited to wage earners in 30 industry classifications. Starting in 1936 the coverage was extended to include all employees in all types of manufacturing.

[2] The frequency rates shown (average number of disabling injuries for each million employee-hours worked) represent the combined experience of all reporting establishments in each year. Prior to 1936 the frequency rates were unweighted. From 1936 on, the all-manufacturing rates have been weighted averages. In their computation the current procedure is to weight the frequency rate for each industry classification by he estimated total employment in that industry.

[3] Prior to 1937 the index numbers represent the change in the frequency rate of the entire reporting sample for each year as related to the base year, 1926. Because of the substantial expansion of the sample in 1936 and in subsequent years this procedure was changed. Beginning with 1937, the indexes have been computed by chain link methods using the percentage of change in the frequency rates for identical establishments in each pair of successive years. The index changes, therefore, do not necessarily correspond with the changes in the all-manufacturing frequency rates shown in the table.

TABLE G–4: Work-injury frequency rates for selected manufacturing and nonmanufacturing industries, 1941–47

Industry	Injury frequency rate[1]						
	1941	1942	1943	1944	1945	1946	1947
Manufacturing							
Total manufacturing	[2]18.1	[2]19.9	[2]20.0	[2]18.4	[2]18.6	[2]19.9	18.8
Apparel and other finished textile products:							
Clothing, men's and boys'	6.7	7.7	7.6	9.2	8.4	7.6	7.0
Chemicals and allied products:							
Drugs, toiletrics, and insecticides	9.0	15.4	18.5	18.6	14.9	14.2	12.0
Explosives	5.7	6.4	5.3	5.3	3.6	5.7	5.3
Fertilizers	27.7	32.0	32.6	33.7	33.5	33.0	31.6
Paints, varnishes, and colors	14.8	17.4	19.0	18.3	17.6	18.6	17.3
Soap and glycerin	10.9	10.3	11.4	15.0	11.6	10.7	9.4
Synthetic textile fibers	9.6	8.4	10.5	9.0	8.9	6.8	5.8
Electrical machinery, equipment, and supplies:							
Radios and phonographs	6.2	5.9	7.9	9.2	6.8	7.4	6.2
Food products:							
Baking	15.0	16.2	20.5	20.2	18.6	18.1	18.1
Canning and preserving	30.0	33.0	25.3	28.9	27.2	30.7	27.3
Confectionery	16.1	15.2	19.4	19.0	18.1	17.4	16.1
Flour, feed, and grain-mill products	21.8	24.9	30.2	31.1	27.6	26.6	27.1
Slaughtering and meat packing	30.9	44.8	47.6	35.9	32.4	35.7	29.9
Sugar refining	28.2	31.4	29.9	31.6	30.3	33.6	32.8
Furniture and finished lumber products:							
Furniture, metal	21.4	23.0	30.7	30.2	21.2	21.1	19.6
Morticians' supplies	13.6	17.2	21.3	17.8	18.7	24.7	25.0
Office, store, and restaurant fixtures	21.7	18.2	27.1	21.0	26.3	27.9	23.9
Iron and steel and their products:							
Cutlery and edge tools	20.7	24.5	25.9	28.1	26.0	23.0	23.6
Fabricated structural steel	35.7	40.7	34.7	35.7	27.6	29.3	27.3
Forgings, iron and steel	44.5	38.0	40.8	37.7	32.5	31.2	28.4
Hardware	19.4	24.3	20.2	20.0	16.6	13.8	16.0
Heating equipment, not elsewhere classified	29.6	33.7	36.3	42.8	33.8	36.0	34.3
Iron and steel	10.2	10.4	10.0	9.9	8.7	9.5	8.2
Ornamental metalwork	18.4	30.2	31.9	32.4	26.2	23.1	27.8
Plumbers' supplies	17.7	20.1	21.9	20.8	16.4	20.2	23.3
Stamped and pressed metal products, not elsewhere classified	29.1	20.6	28.8	27.4	22.2	22.7	23.4
Tin cans and other tinware	21.0	20.3	17.3	19.7	17.3	17.1	18.6
Tools except edge tools	24.9	24.3	25.5	25.5	22.8	24.8	23.7
Wire and wire products	19.0	21.6	21.4	23.2	23.1	23.7	21.5

[1] The frequency rate is the average number of disabling injuries for each million employee-hours worked.

[2] Weighted according to estimates of total current employment in each industry.

Section H: Building and Construction

A number of statistical measures of building and construction activity are prepared regularly by the Bureau of Labor Statistics.

The series on new construction activity compiled by the Bureau of Labor Statistics in cooperation with the Office of Domestic Commerce, U. S. Department of Commerce, gives detailed information on estimated expenditures for new construction, by type of project, such as highway and road work; public utility construction; river, harbor, and flood control; as well as on residential and nonresidential building.

For federally financed construction, the expenditures are also segregated according to different kinds of projects.

Special compilations are made for the measurement of volume (by value) of building construction—residential, nonresidential, and additions, alterations, and repair work. Such construction forms the largest segment of all construction volume.

Construction Expenditures

The construction-expenditures estimates provided by the Bureau of Labor Statistics (table H–1) measure the total dollar value of construction work actually performed or "put in place" from 1915 to 1947, by type of construction. They differ from data pertaining to building permits (tables H–4 and H–5) which cover the value of work scheduled to be started; they also differ from the data on Federal contract awards and force-account work started (tables H–2 and H–3).

Included in the expenditures estimates are total payments to labor, the value of material consumed, and contractors' overhead and profit on all types of construction projects in progress. The installed value of equipment considered an integral part of a structure is also included; the value of land, machinery, and moveable equipment is excluded. The value of major additions and alterations is combined with the value of new construction in table H–1. Minor building repairs and maintenance work (such as painting, plumbing and heating, waterproofing, papering, electrical repairs, etc.) are excluded.

A summary of the sources and methods used in compiling the expenditures estimates in table H–1 for the principle types of construction follows:

Since 1921, urban private residential construction estimates have been based on reports of building permits issued, submitted by local building officials. These data are adjusted for residential building activity in nonreporting permit places and nonpermit-issuing places, abandonments, and the understatement of construction costs inherent in building permit valuations. From January 1945, adjustments have been made for the time which elapses between the issuance of the building permit and the start of construction. Rural nonfarm starts estimates are based on ratios derived from the analysis of current building permit reports for rural nonfarm places and field surveys in a limited number of nonpermit issuing places. (For a more detailed discussion of these procedures, see the description for the estimates of total nonfarm housing started, in Section I on Housing and Rents).

The resulting total nonfarm estimate of the value of work started during each month is then spread over the construction period based on current progress surveys. The expenditures thus obtained for specific months are then totaled. The 1915–20 estimates are carried back from the 1921–22 average by using the relative changes indicated in the value of residential building contracts awarded as reported by the F. W. Dodge Corp.

Separate estimates are made for the new private nonresidential buildings (industrial warehouses, offices, and loft buildings; stores, restaurants, and garages; religious structures; educational buildings; hotels; social and recreational buildings; hospitals and institutions; and miscellaneous) from the record of contracts awarded as reported monthly by the F. W. Dodge Corp. Adjustments are made to allow for under-coverage in the Dodge reports (which cover only the 37 Eastern States and exclude small projects), and for canceled contracts and duplication of public utility building construction, and then converted to a work-put-in-place basis.

Annual estimates of farm construction and maintenance were made by the Bureau of Agricultural Economics and published in the United States Department of Agriculture study, Income Parity for Agriculture, Part II, Sec. 5 (March 1941). Separate estimates were prepared for operators' dwellings and for service buildings, which correspond respectively to residential and nonresidential construction. Maintenance is included in these figures, however. To segregate the figures for the new construction group, estimates of farm consumption of lumber, prepared by the Forest Service of the United States Department of Agriculture, were utilized.

The gross capital expenditures of class I railroads for equipment, road, and structures for 1922–47 are obtained from the annual Review of Railway Operations, published by the Association of American Railroads. Estimates of construction expenditures of all railroads are obtained by upward adjustment of the data for class I railroads on the basis of the total investment in road and structures of class I railroads and of all railroads. Annual statistics on capital expenditures of the transit industry for 1922–47 are based on data in the Transit Fact Book published by the American Transit Association. The estimates of the railroads and transit industries are carried back to 1915–21 by using expenditure data based on miles of track added or rebuilt.

Annual additions to electric power plants reported to the Federal Power Commission since 1937 are adjusted to include small nonreporting companies and to allow for work in progress and the purchase of existing property, and electric light and power construction financed by the Rural Electrification Administration since 1936 is obtained from the annual reports of that agency. Edison Electric Institute reports are used for 1921–36. The estimates for 1915–20 are based on a year-by-year distribution of increments in plant and equipment as indicated by the Census of Electrical Industries for 1912, 1919, and 1922. Construction expenditure data, published annually since 1929 by the American Gas Association, are adjusted to eliminate equipment expenditures. The 1915–28 estimates for this industry were carried back by use of the year-to-year changes in the fixed capital accounts of 50 large companies.

Estimated construction expenditures of the telephone industry were obtained from the American Telephone and Telegraph Co. Those for the telegraph industry were derived from capital expenditures reported by the Western Union Telegraph Co. for 1927–47 and by Postal Telegraph and Cable Co. for 1919–43, with an adjustment back to 1915 made on the basis of annual increments in the value of plant and equipment. Expenditures for pipe lines are obtained from reports filed with the Interstate Commerce Commission, with adjustment made for companies not required to report and for purchase of existing lines.

From 1939, public residential construction estimates have been based upon regular progress reports issued by the Federal Public Housing Authority and other public housing agencies listing the value of work put in place for individual projects. Adjustments are made to cover funds contributed to the Federal projects by local agencies. Expenditures by the United States Housing Corporation for 1919–20, and by the Public Works Administration, Resettlement Administration, and Alley Dwelling Authority from 1934 are compiled from the annual reports of these agencies.

Estimates through 1941 were based on the F. W. Dodge Corp. reports of contracts awarded for public nonresidential buildings. From 1942 on, estimates were based on construction progress reports furnished by Federal agencies, supplemented by the Dodge Corp. reports.

For 1940–47, construction expenditures of the War and the Navy Departments have been based upon engineers' progress reports issued by these agencies. Navy Department construction expenditures for 1915–36 are derived from special tabulations of the Bureau of Supplies and Accounts, United States Navy Department. Expenditures of the Navy for 1937–39 and the War Department for 1915–39 are based upon expenditures shown in the Budget of the United States Government.

Since 1921, construction estimates for State administered highways are based on annual reports of the Bureau of Public Roads. State administered highway estimates are adjusted to include expenditures by county, municipal, and other local bodies. The adjustments are based upon ratios developed from the analysis of total highway construction and State highway construction. Estimates from 1915 to 1920 are derived from the 1920 Department of Agriculture Yearbook. Interim monthly estimates of expenditures are derived by converting the number of man-months worked as reported by the Bureau of Public Roads into value of work performed.

Construction estimates for water supply and sewage disposal systems are based upon data published annually by the Bureau of the Census in Financial Statistics of Cities. Using the expenditure patterns of the city size groups reporting, expenditure ratios were derived for the smaller municipalities and rural incorporated areas. Current estimates are based upon contracts awarded as reported by F. W. Dodge Corp. with adjustments for incomplete coverage.

For 1915–42, expenditures for reclamation, improvement of rivers and harbors, and flood-control work are derived from annual reports of the Army Chief of Engineers and the Commissioner of Reclamation. From 1943, estimates are based upon project reports furnished by these agencies. Tennessee Valley Authority expenditures are available in its annual reports. Indian Service, Forest Service, National Park Service, and Soil Conservation Service expenditures are derived from special tabulations prepared by those agencies and from the Budget of the United States Government.

Construction expenditures figures of all Federal agencies not discussed above are derived from the Budget of the United States Government.

Outlays for municipal public service enterprises are obtained directly from the municipality or estimated on the basis of information reported in Financial Statistics of Cities. Current "all other" non-Federal construction estimates are derived primarily from reports of contracts awarded which are compiled by F. W. Dodge Corp., Engineering News-Record, and other publications reporting contract awards.

TABLE H-1: Estimated expenditures for new construction by type of construction: years 1915–47 and months 1939–47[1]

Type of construction	Expenditures (in millions)

[1] Construction expenditures represent the monetary value of the volume of work accomplished during the given period of time. Estimates of expenditures for 1915 through 1938 were made by the Office of Domestic Commerce, U. S. Department of Commerce, except for the nonfarm residential building segment, which was estimated by the Bureau of Labor Statistics. For 1939 and subsequent years, the estimates were prepared jointly by the Bureau of Labor Statistics and the Office of Domestic Commerce.

[2] Includes major additions and alterations.

[3] Excludes nonresidential building by privately owned public utilities.

[4] Not available separately; included in total.

[5] Excludes nonresidential building for military and naval facilities.

[6] Excludes expenditures to construct facilities used in atomic energy projects.

[7] Public industrial and commercial building not segregable from private for 1920 through 1932, but the amount involved is negligible.

[8] Includes primarily roads in national parks and forests. Federal contributions to State and local programs are included in those categories, which are shown above according to government ownership.

[9] Covers primarily publicly owned electric light and power systems and local transit facilities.

[10] Covers miscellaneous construction items such as airports, monuments, memorials, etc.

[11] Less than $500,000.

[12] Includes social and recreational buildings, hotels, and miscellaneous buildings not elsewhere classified.

Value of Federal Construction

Federal contract award data compiled by the ureau of Labor Statistics represent the total alue of work under contract that was planned r was to be started immediately or in the near uture. Also included in the totals is the value f Federal force–account work actually started. hese figures were obtained from Federal Gov-rnment progress reports.

Force–account employees are workers hired, not through a contractor, but directly by a business or government agency, and utilized as a separate work force to perform nonmaintenance construction work on the agency's own properties.

Table H–2, which shows the value of contracts awarded and force–account work started on federally financed construction, by type of project, covers 1935–47 and table H–3, giving the data by State, is for 1943–47.

Table H–2: Value of contracts awarded and force-account work started on federally financed construction by type of project, 1935–47[1]

Period	Value (in thousands)									
	All types of projects	Airports[2]	Buildings[3]		Conservation and development		Electrification[4]	Highways, streets, and roads	Water and sewage	All other types[5]
			Residential	Non-residential	Reclamation	River, harbor, and flood control

---

[1] Covers projects financed wholly or partially from Federal funds. Excludes off-continent construction beginning with January 1943. Projects classified as secret by the military are excluded.

[2] Excludes hangars and other buildings, which are included under building construction.

[3] Includes additions, alterations, and repairs.

[4] Excludes loans granted by the Rural Electrification Administration, which were included in this series in publications issued prior to August 1947.

[5] Covers forestry, railroad construction, and other types of heavy engineering projects not elsewhere classified.

[6] Included in "All other types."

[7] Nonresidential construction at the site of three Resettlement Administration projects for which a breakdown of residential and nonresidential costs is not available is included in the residential totals.

TABLE H-3: Value of contracts awarded and force-account work started on federally financed construction, by State, 1943–47[1]

[1] Covers projects financed wholly or partially from Federal funds. Projects classified by the military as secret are excluded.

Value of Urban Building

The estimates of the volume (by value) of urban building construction are based primarly on local building permit reports received monthly by the Bureau of Labor Statistics from approximately 2,500 urban places which contained approximately 85 percent of the total 1940 urban population.

Urban, as defined by the Bureau of the Census covers all incorporated places of 2,500 population or more in 1940 and, by special rule, a small number of unincorporated civil divisions. Such estimates measure intentions to build rather than work actually started.

The building permit reports which are received give the total number of individual structures (by type) for which such permits were issued during the month, the valuation of these structures as shown on the permits, and the number of family-dwelling units to be provided in new housekeeping structures.

To obtain the estimates shown in tables H–4 and H–5 for the entire urban United States, all urban places and the reporting urban places are first classified by State, city population group, and location in or outside metropolitan districts. Estimates are then computed for all places in each of these categories by applying to the reported permit data the ratio between the total number of places and the number reporting. The coverage is usually complete in places of 25,000 population or over. For places of 5,000 to 25,000 population, the number reporting is usually less than one-third complete. For places of 2,500 to 5,000 population, the sample is usually not less than one-eighth.

The data on total urban permit valuation, obtained through this weighting process, have not been adjusted for the understatement of actual construction costs ordinarily found to exist in valuations shown on permits. Although some urban places do not require permits to build, the procedure followed to derive estimates for all urban places combined results in the inclusion of data for these nonpermit places which are comparable to permit figures (i.e., an estimate of permit volume for these places if permit systems had been in operation). No allowance is made in the urban permit figures for the lag between permit issuance and start of construction and for some permits which do not result in construction. Since local building permits are not issued for Federal building construction projects, information received from Federal agencies on building construction contracts awarded and value of force-account work started (see tables H–2 and H–3) has been added to the local building permit estimate to obtain the total urban estimate.

Estimated permit valuation of urban building construction is shown in table H–4 by source of funds and class of construction for 1942–47, and in table H–5 the data are shown by State for 1942–47.

NOTE: Upon request, the Bureau of Labor Statistics will supply detailed tables showing permit valuation of building construction and number of new dwelling units in cities having (in 1940) 100,000 population or more. Data are given for the period 1921–47 covering value of all classes of building construction, with separate statistics for new nonresidential and new residential building and the total number of dwelling units.

TABLE H–4: Estimated permit valuation[1] of urban building construction[2] authorized, by source of funds and by class of construction, 1942–47

Period	Valuation (in thousands)											
	TOTAL						NON-FEDERAL[3]					
	All building construction	New residential building			New nonresidential building	Additions, alterations, and repairs	All building construction	New residential building			New nonresidential building	Additions, alterations, and repairs

---

[1] Includes value of Federal construction contracts awarded and estimates for building to be started in urban places which do not issue permits.

[2] Urban, as defined by the Bureau of the Census, covers all incorporated places of 2,500 population or more in 1940 and, by special rule, a small number of unincorporated civil divisions.

[3] Covers private and State and local government but excludes New York City Housing Authority projects which, for consistency in handling all public housing, are classified with Federal housing construction.

ABLE H-5: Estimated permit valuation[1] of urban building construction[2] authorized, by source of funds, by class of construction, and by State, 1942-47

---

[1] Includes value of Federal construction contracts awarded and estimates for building to be started in urban places which do not issue permits.

[2] Urban, as defined by the Bureau of the Census, covers all incorporated places of 2,500 population or more in 1940 and, by special rule, a small number of unincorporated civil divisions.

[3] Includes value of dormitories and other nonhousekeeping residential buildings.

[4] Covers private, and State and local government but excludes New York City Housing Authority projects which, for consistency in handling all public housing, are classified with Federal housing construction.

[5] Data for Boston are based on permit applications filed.

[6] New York City data for 1921 through 1944 are based on applications filed rather than on permits issued. For the years 1942 through 1944 large projects which were definitely determined to represent postwar plans have been deleted. Figures for 1945 to date are based on inspection records and represent work actually started.

Section I: Housing and Rents

Nonfarm Dwelling Units

All Bureau of Labor Statistics estimates of the number of new dwelling units provided exclude the construction of housing on farms. For the urban and rural nonfarm portions of the country a number of series are prepared.

A new dwelling unit is a complete family accommodation built at a new location from new or re-used material.

Publicly financed units are those built with Federal Government and with other public funds.

Privately financed units are those built with private funds.

Publicly and privately financed units make up the total built with funds from all sources.

By Census definition, urban means all incorporated places of 2,500 population or more in 1940 and, by special rule, a small number of unincorporated civil divisions.

Nonfarm areas include urban areas and rural territory, except farms.

Estimates of the total number of new nonfederally financed permanent dwelling units which were started, under construction, and completed each month beginning with January 1946 in all nonfarm places are shown in table I–1. Both conventional and prefabricated types of permanent units are included. The table excludes all units provided by the conversion of existing structures and by the building of dormitory accommodations, trailers, military barracks, and temporary structures.

For all urban places, estimates of housing starts are based primarily on permit data for urban building (see tables H–4 and H–5). The data contained in the tables to which reference is made reflect intentions to build, rather than actual starts. In the compilation of table I–1, adjustments have been made to allow for some permits which do not result in construction and for the time that usually elapses between the issuance of a permit and the actual start of construction. Such adjustments are based on housing data obtained from permit offices and from contractors contacted in field surveys covering all permit-issuing places of 65 sample areas throughout the United States. The 65 sample areas include 28 large industrial areas (groups of counties surrounding large industrial cities), 21 urban counties with medium-sized or small cities, and 16 predominantly rural counties.

For all rural nonfarm places, estimates of housing units started are based on data collected in field surveys in both permit and nonpermit places of the 65 sample areas previously mentioned. (Starts information for nonpermit places in these areas is obtained by Bureau of Labor Statistics agents from contractors, materials dealers, loan organizations, others familiar with building activity in these localities, and by personal observation). Each month, after obtaining the ratio of housing starts in rural nonfarm places to the number in urban places in these 65 representative areas, this ratio is applied to the estimate of starts for all urban places. The resulting rural nonfarm estimates are then combined with the urban estimates to provide the estimates of total nonfarm housing starts.

Housing completions have been estimated by distributing the total nonfarm starts figure for each month over the period of months during which completion of the units is estimated to occur. The basis for the distribution of units is the time required to complete housing units as found in the 65 sample areas. The estimated nonfarm completions for a given month consist of all units previously started which were estimated to have been completed in that particular month. Units started before 1946 which were estimated to be completed during that year have been included in the 1946 completions estimates.

The estimates of new dwelling units for nonfarm places given in table I–2 cover all new permanent housing units (conventional or prefabricated) financed either by public bodies (Federal and other) or by private organizations. This table also covers new temporary housing units such as those authorized under the Lanham Act for defense and war housing and under the veterans' emergency re-use housing program by the dismantling of temporary war structures and their re-erection at a new site. Excluded units are those provided by the conversion of existing structures (units in the veterans' re-use program provided by conversion of war structures at their original site are in this category) and by the construction of dormitory accommodations, trailers, and military barracks. Only new permanent dwelling units are shown in table I–3.

Derivation of urban estimates is described on page 181. Unlike the urban data in tables H–4 and H–5, which represent only intentions to build, the data in tables I–1, I–2, and I–3 represent work actually started. Adjustments in tables I–2 and I–3 (based on field surveys in the 65 sample areas discussed above) have been made in the urban figures from January 1945 to date to correct for the cancellation of some permits and the time interval between permit-issuance and actual start of construction; no adjustments were made in the data prior to 1945, when permit lapses and time lags were negligible.

For rural nonfarm places, the estimates of housing units started in 1946 and subsequently were also derived as explained above. Before 1946, the estimates were computed from a ratio of rural to urban starts based on the 1940 housing census and adjusted monthly according to trends indicated by building-permit reports received from rural and certain urban places. The resulting rural nonfarm estimates combined with the urban data described above provide the nonfarm housing estimates.

TABLE I–1: Estimated number of new permanent nonfarm[1] family dwelling units started, completed, and under construction, 1946–47[2]

Period	Number of new dwelling units			Number of new dwelling units		
	Started	Completed	Under construction[3]	Started	Completed	Under construction[3]
	1946			1947		
January	[4]37,500	15,900	159,100	[4]39,300	62,600	346,900
February	42,400	17,300	184,200	42,800	60,300	329,400
March	62,000	18,700	227,500	56,000	57,600	327,800
April	67,000	21,000	273,500	67,100	59,200	335,700
May	67,100	25,100	315,500	72,900	59,400	349,200
June	[4]64,100	30,600	349,000	77,200	62,300	364,100
July	[4]62,600	36,700	374,900	81,100	64,800	380,400
August	[4]65,400	43,400	396,900	[4]86,300	69,600	397,100
September	57,600	49,700	404,800	[4]93,800	76,700	414,200
October	[4]57,800	55,500	407,100	[4]94,000	82,700	425,500
November	47,700	61,200	393,600	[4]79,700	86,500	418,700
December	39,300	62,700	370,200	[4]58,800	90,000	387,500

[1] The geographic coverage of this table is broader than that of tables H–4 and H–5, covering urban areas. In addition to the urban areas of 2,500 population or more in 1940 and, by special rule, a small number of unincorporated places, nonfarm areas include all rural areas other than farms.

[2] Data are based on building permits issued, adjusted for lapsed building permits and the time lag between issuance of permits and dates of starts. Included are estimates for dwelling units started in rural nonfarm areas, based on building permits issued and special field surveys in 65 areas. The estimates shown in this table do not include dwellings provided by conversion of existing structures, or trailers and temporary accommodations, regularly included by the National Housing Agency in its reports on the progress of the Veterans' Emergency Housing Programs.

[3] It is estimated that on December 31, 1945, dwelling units under construction totaled 137,500.

[4] Included are the following number of new dwelling units started by the New York City Housing Authority: January 1946, 608; June, 1,338; July, 1,310; August, 3,485; October, 1,286; January 1947, 1,084; August, 192; September, 192; October, 460; November, 650; December, 364.

TABLE I-2: Estimated number of new nonfarm[1] family dwelling units started, by source of funds and permanency of publicly financed units, 1935–47 (privately and publicly financed)

Period	Total new dwelling units	Privately financed units	Publicly financed units		
			Total	Permanent	Temporary and demountable

[1] The geographic coverage of this table is broader than that of tables H-4 and H-5 covering urban areas. In addition to the urban areas of 2,500 population or more in 1940 and, by special rule, a small number of unincorporated places, nonfarm areas include all rural areas other than farms.

[2] Such housing consists principally of defense and war housing authorized under the Lanham Act, as amended.

[3] The data for 1945 and subsequent years represent a revision of previous estimates of the Bureau of Labor Statistics to allow for lapsed building permits and for lag between issuance of permits and actual start of construction. These factors were negligible prior to 1945.

[4] Includes those units in the Veterans' Emergency Housing Program provided by dismantling temporary war structures and their re-erection at a new site.

TABLE I-3: Estimated number of new permanent family dwelling units started in nonfarm areas,[1] by source of funds, and by type of structure, 1920–47[2]

Period	Total nonfarm units[3]	Area[4]		Privately financed units	Publicly financed units	Units in —		
		Urban	Rural nonfarm			1-family structures	2-family structures[5]	Multifamily structures[6]
1920	247,000	196,000	51,000	247,000	0	202,000	24,000	21,000

---

[1] The geographic coverage of this table is broader than that of tables H–4 and H–5 covering urban areas. In addition to the urban areas of 2,500 population or more in 1940 and, by special rule, a small number of unincorporated places, nonfarm areas include all rural areas other than farms.

[2] Data for 1920-29 are from the National Bureau of Economic Research; data for 1910-19 and 1930-47 from the Bureau of Labor Statistics. No break-downs are available for 1910-19. Bureau of Labor Statistics data are based on building permits issued and Federal construction contracts awarded which, from 1946, have been supplemented by data from field surveys in nonpermit-issuing places. Beginning in 1945, data from building permits have been adjusted for lapsed permits and lag between permit issuance; and the start of construction. These influences were negligible prior to 1945.

[3] Total nonfarm units scheduled for earlier years (in thousands): 1910—475; 1911—480; 1912—490; 1913—455; 1914—445; 1915—475; 1916—480; 1917—230; 1918—120; and 1919—330.

[4] Urban and rural nonfarm classifications for years 1920-29 are based on 1930 Census: for years 1930-47, on 1940 Census.

[5] Includes 1- and 2- family dwellings with stores.

[6] Includes multifamily dwellings with stores.

Dwelling Units by Type of Occupancy

Data were collected by the Bureau of Labor Statistics showing the relative importance of each type of occupancy of dwelling units in 157 areas at a stated period during 1944–46. The purpose of the studies was to provide the basis for periodic reviews of the samples of rental dwellings on which the Bureau's residential rent indexes are based and to secure occupancy and vacancy data for the National Housing Agency. These surveys of residential dwellings were conducted in combination with regular rent surveys made by the Bureau of Labor Statistics, as part of its study of changes in consumers' prices and living costs for moderate-income city families. Information was obtained by personal visits to occupants of family dwellings in a sample carefully selected to represent all sections and all types of structures in each area. In general, these surveys included all quarters normally considered as dwelling units except public housing, commercial rooming houses and hotels, trailers and tourist cabins, and miscellaneous quarters such as boats and tents.

The cities covered (see table I–4) are not intended as a representative sample of all cities in the country. Selection of cities for survey (either by the Bureau of Labor Statistics or the Bureau of the Census) was based on the need for housing information. Most of the cities which were covered had serious housing shortages at some period during World War II. Nevertheless, the group included more than half of all cities having 100,000 population or more in 1940, exclusive of New York and Chicago.

TABLE I-4: Distribution of family dwelling units by type of occupancy for 157 areas, selected periods 1944–46

Area	Date of survey	Estimated number of dwellings	Percent of dwellings		
			Tenant-occupied	Owner-occupied	Vacant
Alabama:					
Birmingham	Sept. 1944	77,000	63.6	35.9	0.5
Mobile	April 1945	26,000	55.1	44.0	.9
Arkansas:					
Batesville	April 1945	1,206	38.9	60.0	1.1
El Dorado	Oct. 1945	5,000	52.9	45.7	1.4
Hot Springs	Oct. 1945	7,000	59.3	40.5	.2

---

[1] City surveyed by the Bureau of the Census in 1945 and 1946.

[2] Percentage is for that portion of the city corresponding to city limits as of April 1940.

[3] Tenure rates for Suisun City are not included in percentages.

[4] Percentage is for city proper only.

[5] Percentages for Minneapolis and St. Paul cities proper.

[6] Dayton area is Dayton-Oakwood section.

[7] The Greater Providence area includes Pawtucket, Cranston, Warwick, East Providence Town, North Providence Town, and West Providence Town; excludes Providence City.

Rentals, Maintenance, and Repairs

Annual average indexes of residential rents paid by moderate-income families in large cities and of the retail prices of fuels important in residential heating are shown in table I–5.

The rent indexes are components of the Bureau of Labor Statistics consumers' price index for moderate-income families in large cities (described in detail on p. 104), and represent average changes in rents for the same dwellings with the same facilities and services from one time to another. Data are collected at regular intervals from approximately 45,000 tenant families. In computing the indexes, proper representation is given to various grades of housing normally rented by the middle income group. Data for the cities are combined on the basis of relative populations in each city included.

The indexes of retail prices of fuels used in residential heating were discontinued after the computation of June 1947 data because of reduced appropriations. These indexes were designed to measure changes in average prices of major types of residential heating fuels in 55 cities. Anthracite, bituminous coal, coke, kerosene, fuel oil, gas, and wood were included in the series. Prices for the various fuels were combined on the basis of weighting data secured from the Bituminous Coal Division, United States Bureau of Mines, and the Fuel Oil Ration Division of the Office of Price Administration. The weights are representative of the 1939–40 patterns of fuel consumption with adjustments for significant shifts in consumption since that time. Data for the individual cities were combined on the basis of fuel consumption in each city. Indexes also were computed for each of the 55 cities and for major types of fuels.

Average contract rents in private residential dwellings in 57 areas are shown in table I–6. These areas were surveyed in 1945 by the Bureau of Labor Statistics and the Bureau of the Census to obtain needed housing data for the National Housing Agency. The cities included were chosen because of special housing problems existing in the areas at the time of the survey. Thus, they do not represent a properly distributed sample of all cities in the country. Nevertheless, a significant proportion of the major cities in the country were covered.

TABLE I–5: Indexes of rents and fuel costs, 1939–47

Period	Residential rents for moderate-income families in large cities (1935-39 = 100)	Retail prices of fuels used in residential heating (1939 = 100)
1939	104.3	100.0
1940	104.6	103.4
1941	106.2	107.3
1942	108.5	114.4
1943	108.0	120.4
1944	108.2	123.7
1945	108.3	123.9
1946	108.6	130.9
1947	111.2	[1]142.6

[1] Six months' average from January to June; the series was discontinued as of July 1947.

TABLE I-6: Contract monthly rent for tenant-occupied privately financed residential dwellings in 57 cities surveyed in 1945[1]

Area	Date of survey	Estimated number of all dwellings	Tenant-occupied dwellings		
			Contract (median) monthly rent	One-fourth rented at or less than—	One-fourth rented at or more than—
Aberdeen area, Wash.[2]	Aug. 1945	11,000	$22.00	$16.00	$30.00
Albany and Corvallis, Oreg.[2]	Aug. 1945	5,500	30.00	23.00	40.00

[1] The rental data presented in this table are not comparable with the figures on changes in rents published by the Bureau of Labor Statistics in its consumers' price index (see table D-1). The index reflects changes in rent charged for the same dwelling with the same services and facilities. The rents included in this table represent the averages for rental units at the time of the survey. Comparisons of these average rents with averages obtained from similar previous surveys reflect, in addition to changes in rents shown in the index, shifts in the size and type of rental units, and changes in the items included in the contract rent.

[2] Surveyed by the Bureau of the Census. All others were surveyed by the Bureau of Labor Statistics.

[3] Not available.

Section J: Social Security and Related Programs

The Social Security Administration has compiled the information in table J–1, which deals with operations under various social security and related programs in effect from 1937 through 1947.

In addition to giving the amount of benefits and the number of beneficiaries and recipients under insurance and public assistance programs, the table shows the number of persons engaged in work under the Work Projects Administration, the Civilian Conservation Corps, and the National Youth Administration from 1937 until the time of liquidation of these programs.

Beneficiaries of old-age and survivors insurance represent the number in current-payment status at the end of December; amounts are payments certified to the Treasury Department, and include retroactive payments.

Railroad retirement benefits represent employee annuities in addition to pensions to former carrier pensioners. Beneficiaries are as of the last day of December in current-payment status, and amounts are payments certified, including retroactive payments. Data for 1937–39 on railroad annuitants retired for disability are estimated on the basis of reported data for 1940.

Railroad unemployment insurance beneficiaries represent the average number of persons receiving benefits in a 14-day registration period; amounts are adjusted for underpayments and recovery of overpayments.

No data are available on the number of beneficiaries receiving workmen's compensation. Amounts are estimated, and exclude payments for medical care; monthly survivor benefits include a small but undetermined amount of lump-sum death payments.

Federal, State, and local government retirement payments (included in the classification "Other") exclude refunds of employee contributions. The Civil Service Commission retirement and disability benefits include survivor payments under joint and survivor elections. The break-down between retirement and disability benefits is estimated. Payments are principally from the civil-service retirement and disability fund, but also include payments from the Canal Zone and Alaska Railroad retirement and disability funds administered by the Civil Service Commission.

The Veterans Administration separations of retirement and disability payments are estimated on the basis of fiscal-year data; payments for 1937–39 were distributed according to the 1940 distribution. The bulk of these payments are for disability; retirement benefits are for Spanish-American War veterans retired for age.

State unemployment insurance beneficiaries represent the number during an average week in December; benefit payments are adjusted for voided benefit checks.

Servicemen's readjustment allowances for unemployment under title V of the Servicemen's Readjustment Act (the GI Bill of Rights), began in September 1944. Beneficiaries represent the average weekly number during December; amounts are gross and have not been adjusted for voided benefit checks.

Self-employment payments, also made under title V of the Servicemen's Readjustment Act, were first payable in November 1944. Self-employed veterans receive $100 a month less net earnings from their business or profession. Beneficiaries represent the number of veterans paid during December.

Under "Other" programs, specific risks included are as follows:

(1) Old-age retirement covers Federal civil-service programs, other contributory programs (Federal Reserve, Foreign Service, Tennessee Valley Authority, and the Examining Division of the Bureau of the Comptroller of the Currency), noncontributory retirement programs (Army, Navy, Coast Guard, Marine Corps, Coast and Geodetic Survey, Public Health Service, Federal judges, and Lighthouse Service), State and local government programs, and pensions under the Veterans Administration program to Spanish-American War veterans retired for age.

(2) Survivorship statistics are for Federal civil service, State and local government, and workmen's compensation.

(3) Disability includes Federal civil service, State and local government, and sickness compensation under the Rhode Island and California laws and the Federal railroad unemployment insurance law. Sick benefit payments began in April 1943 in Rhode Island, in December 1946 in California, and in July 1947 for railroad workers.

"Other public assistance programs" represents subsistence payments to farmers under the Farm Security Administration program (through June 1942) and general assistance payments. Recipients in this group represent the number of cases rather than the number of different individuals.

NOTE: For a summary of the number of continued claims under the State unemployment insurance program and under the program of veterans' readjustment allowances, see table A–13.

TABLE J-1: Selected data on social security and related programs, 1937–47[1]

[Corrected to July 30, 1948]

---

[1] Data partly estimated; for 1947, preliminary and subject to revision; slight differences between subtotals and totals result from rounding of figures.

[2] Represents in large part retirement programs for Federal, State, and local government employees; veterans' pensions are also included.

[3] Not available.

[4] Survivor programs for Federal, State, and local government employees and workmen's compensation. Workmen's compensation includes a small but undetermined amount of lump-sum death payments.

[5] Includes old-age and survivors insurance; railroad retirement; Federal, State, and local government retirement; and veterans' program.

[6] Excludes payments for medical care.

[7] Disability programs for Federal, State, and local government employees, and sickness compensation under Rhode Island and California laws. Also includes 11.4 million dollars in benefit payments to 31,200 beneficiaries covered by railroad sickness insurance (number of beneficiaries represents an average 14-day registration period in December 1947).

[8] For unemployment only.

[9] Allowances to self-employed veterans under the Servicemen's Readjustment Act.

[10] Less than $500,000.

[11] Subsistence payments to farmers from 1937 to June 1942, and general assistance for all years.

[12] Beneficiaries represent number who were in current-payment status at the end of December.

[13] Average weekly number.

[14] Average number during a 14-day registration period.

[15] Number during the month. (See also footnote 8.)

[16] Although payment is shown for the year, program ended as follows: For the Civilian Conservation Corps, June 1942; Work Projects and National Youth Administrations, June 1943

Source: Federal Security Agency, Social Security Administration, Division of Research and Statistics. For detailed data, see the Social Security Yearbook, 1947.

Section K: Consumers' Cooperatives

Consumers' cooperative associations are nonprofit organizations, owned and controlled by the consumers of their services. They provide whatever goods or services the members desire. Their major characteristics are that (1) membership is open to all who can use their facilities, (2) each member has one vote only, regardless of his capital investment in the enterprise, (3) share capital receives a fixed rate of interest and never rises above par, and (4) savings (earnings) made by the enterprise, after payment of operating expenses, are returned to the patrons in proportion to their patronage of the business.

Data on membership and volume of business for local cooperatives and their federations, compiled by the Bureau of Labor Statistics for selected years from 1929 through 1946, are given in table K–1. Most of the figures for the local associations are estimates based on a reporting sample varying from 1,200 to 1,500 associations; the estimates are checked and corrected periodically when Nation-wide surveys are made by the Bureau. The data for credit unions are exact statistics obtained each year from the Federal Credit Union Division and from the State banking and insurance officials charged with the supervision of these associations. Figures for the electricity cooperatives are furnished to the Bureau by the Rural Electrification Administration. The federations are circularized by the Bureau of Labor Statistics each year; for them the coverage is practically complete and the data for the most part are exact, not estimated.

TABLE K–1: Estimates of number of cooperative associations, membership, and business, by type of association, selected periods 1929–46[1]

Type of association	1929	1936	1940	1944	1945	1946
Local associations	Number of associations					
Retail distributive	1,114	3,600	3,700	4,285	4,550	4,565

[1] Some revisions in data previously published, on basis of later information.

[2] Such as consumers' dairies, creameries, bakeries, propane gas associations, lumber yards, fuel yards, etc.

[3] Local associations only; does not include associations of federated type (which are included with service federations) or funeral departments of store associations.

[4] Such as cold storage, water supply, laundry and dry-cleaning, recreation, printing and publishing, etc.

[5] Except for the year 1929, almost all of these are REA associations, data for which were supplied by the Rural Electrification Administration.

[6] Data are for 1944.

[7] Data are for 1936; no information on which to base later estimates.

[8] No data.

[9] Membership figures do not include dependents who are entitled to treatment.

[10] Policyholders.

[11] Gross income.

[12] Amount of loans made.

[13] Premium income.

[14] Data relate only to reporting associations.

Section L: Production, Income, and Expenditures

Industrial Production

The Federal Reserve index of industrial roduction measures changes in the physical olume of production of manufactures and minerals. It does not cover other types of goods nd services and does not reflect price changes. See table L–1.)

The index underwent no major revision after t was first published in 1927 until the recent World War II period. In order to broaden the epresentation of industrial production, a umber of individual series were revised and thers were added in 1940. In 1941, a further evision was made in the index to include the roduction in Government arsenals, quartermaster depots, and shipyards. Further reviions were made in 1943 to include series not reviously covered directly and to replace thers. New seasonal adjustment factors were ntroduced but the general method of computing he index remained unchanged.

The existing index is derived from about 00 individual series relating to 16 groups of manufacturing industries and 2 groups of minng industries. According to the Federal Reserve Bulletin (October 1943): "Some of the individual series are based on statistics of monthly output of materials or finished products while other series relate to consumption or shipments of materials, machinery hours active, or man-hours worked. Statistics of man-hours worked in a number of lines are adjusted to allow for broad changes in output per man-hour, as measured by other data not suitable for use in a monthly production index. Many of the other series are also adjusted to more accurate physical volume figures not available monthly, such as census statistics. All principal groups of industries in manufacturing and in mining are directly represented in the index at some stage in the production process."[1]

Table L–1 gives the indexes of industrial production for the years 1919–47; monthly indexes from January 1946 are given both adjusted and unadjusted. For durable and nondurable manufactures and for minerals, the individual indexes are also shown. The physical volume is the average per working day.

Labor Costs

In summarizing the operating ratios for 86 ndustries including 2,688 corporations, the 'ederal Trade Commission showed as individ-ial ratios the number of cents per dollar of ales that were allotted to direct and indirect abor (see table L–2). Such labor costs do not epresent the total wage and salary costs for he operations covered. Wages and salaries are ncluded in some of the other expense classifi-ations, notably, research and development, elling expenses, and administrative and gen-ral office expenses. However, all labor cost vhich is a direct charge to the cost of goods old is shown in the two labor classifications.

The figures are for 1940 only and it has not een possible to collect similar information for ater years. Therefore, caution should be used n applying the ratios in table L–2 to any cur-ent situation.

The selection of the corporations in the ample was determined by the importance of he industry to the defense and war effort, the umber of firms necessary to obtain a sample overing at least 35 percent of the sales vol-me of widely scattered industries, or 75 per-ent or more of concentrated industries, which-ver was more practicable. The need of certain ational defense and war agencies for statistics vas also taken into consideration.

The industrial operating information collected was classified by major and minor groups as designated by the Standard Industrial Classification issued by the Division of Statistical Standards of the Bureau of the Budget, Executive Office of the President. The information was tabulated by related industry groups so as to avoid disclosing the financial results for any individual corporation. The key to the major industrial groups is reproduced below for the purpose of aiding in the regrouping of related product industries for comparative purposes.

Number and product group:
20—Food and kindred products
21—Tobacco manufactures
22—Textile-mill products
23—Apparel and other finished products made from fabrics and similar materials
24—Lumber and timber basic products
25—Furniture and finished lumber products
26—Paper and allied products
27—Printing, publishing, and allied industries
28—Chemicals and allied products
29—Products of petroleum and coal
30—Rubber products
31—Leather and leather products
32—Stone, clay, and glass products
33—Iron and steel and their products
34—Transportation equipment (except automobiles)
35—Nonferrous metals and their products
36—Electrical machinery
37—Machinery (except electrical)
38—Automobiles and automobile equipment
39—Miscellaneous manufacturing industries

Table L-2: Operating cost ratios, including direct and other labor cost ratios, of 2,688 corporations in 86 industries, 1940[1]

National Income and Expenditures

Revised series on national income and expenditures from 1929 through 1946 were made available by the Bureau of Foreign and Domestic Commerce, United States Department of Commerce in the July 1947 National Income Supplement and the July 1948 issue of the Survey of Current Business. These series incorporate several technical changes in the treatment of components and in the use of statistical procedures, designed to yield an interrelated and consistent system of national income accounting. A forthcoming volume is intended to supplement the summary explanation of the changes in concept and method described in the July 1947 bulletin.

Gross national product or expenditure is the market value of the output of goods and services produced by the Nation's economy, before deduction of depreciation charges and other allowances for business and institutional consumption of durable capital goods.

Gross national product and national income statistics are shown in tables L–3 and L–4.

When the handbook was sent to press, personal income distribution by States (table L–5) was not available on a basis comparable with the national totals shown herein.

The series of personal income statistics in table L–6 replaces what was formerly called income payments to individuals. The new term is believed to be more descriptive for an aggregate that includes, as previously, such items as income in kind, income of proprietors, and rental income; it also includes income of nonprofit institutions and of private pension, welfare, and trust funds. The shift from income payments to individuals to personal income also involves some change in concept.

Retail sales, shown in table L–7, supplement the data on personal consumption expenditures, which are shown in table L–6.

Table L–8 presents corporate profits before and after taxes, as has been shown in the revised series published in the July 1947 Supplement and the July 1948 issue of the Survey of Current Business. The revised series of national income includes corporate profits before, rather than after, taxes. This change was made so that national income will more accurately reflect factor costs of current production.

ncludes construction expenditures for crude petroleum and natural gas drilling.

The classification of purchases of goods and services into war and nonwar conforms, eneral, to the Daily Treasury Statement classification of general and special account enditures. War purchases include also that part of the capital formation of govern- nt enterprises which is attributable to their war activities. Government contributions to the National Service Life Insurance Fund are classified as war; all other government contributions for social insurance, as nonwar.

[3]Consists of sales abroad and domestic sales of surplus consumption goods and materials.

1947	117,724	28,666	89,058

[1] Estimates of retail sales are based on weighted identical samples, adjusted to Census data, supplemented by various retail sale series for specific industries and by sales tax receipts data. Detailed information on the method of estimating may be found in the 1942 Supplement to the Survey of Current Business (pp. 186–187); and in the November 1943 issue of the Survey (pp. 6–14 and 19–20). Estimates and revisions are published currently in the Survey of Current Business.

[1] Special attention should be directed to the following characteristics of the estimates corporate profits before tax, and profits after tax, during recent years. These characteristics are described only in terms of profits before taxes, but they affect also ofits after taxes, since these are obtained as residuals.

(1) Originally reported profits before tax have been reduced to the extent that they ere overstated by amounts subsequently recaptured by the government by renegotiaon of war contracts. Taxes have also been reduced to take account of the reduced tax bility arising from renegotiation.

(2) By shortening the emergency amortization period for war facilities to less than the e-year span initially used, the Presidential Proclamation signed September 29, 1945, rmitted corporations to deduct additional amortization in the years 1941 to 1945 in the mputation of profits for tax purposes. Our estimates of profits and taxes correspond tax law in that amortization has been recomputed for 1941 to 1945, thus reducing ofits and taxes in these years. In contrast, most corporation reports to stockholders arged the entire amount of additional amortization charges against 1945 profits.

(3) Corporate income and excess profits taxes were reduced from the amount rerted on original tax returns for 1943, 1944, and 1945, by estimated amounts of tax edits arising in 1944, 1945, and 1946 from carry-backs of unused excess profits tax edits and net operating losses.

(4) No adjustments have yet been made to take account of tax rebates which may arise from changes in the excess profits tax credit under Section 722 (dealing with claims that profits in the 1936-39 base period were abnormally low) of the Internal Revenue Code. Also, no allowances have been made for the possible effects of reopening renegotiation cases as a result of the reduction in wartime profits caused by the recomputation of emergency amortization charges discussed above.

Corporate profits, tax, dividends and sales data are derived, with certain adjustments, from corporation income tax returns (except for the years 1945 and 1946, for which the estimates are preliminary). During the period 1934 to 1941 each single corporation, with certain exceptions, was required to file a separate return. These were classified industrially on the basis of the principal activity of the corporation. From 1929 to 1933 and from 1942 to date the filing of consolidated returns for affiliated corporations was generally permissible upon payment of a small additional tax. The consolidated group of affiliated corporations was then classified according to the principal activity of the group. Thus discontinuities in the industrial detail of the data occur between 1933 and 1934 and between 1941 and 1942.

[2] Profits received by domestic corporations from foreign branches are here excluded, and are included in the industry of the recipient corporation. Data for their elimination are not available by industry.

Average Income-Tax Payments by Income

Income-tax payments for a married worker supporting an adult and two children were compiled by the Bureau of Labor Statistics from Bureau of Internal Revenue tax forms. The amount of income taxes payable by such families in the income brackets from $1,000 to $10,000 for 1939–47, shown in table L–9, were computed by using Internal Revenue Form 1040, Individual Income Tax Return (long form) and applying to it allowances for deductible expenses, personal exemption, credit for dependents, and earned-income credit provided by Internal Revenue Tax Form 1040A (short form).

Allowances were made for deductible expenses of 6 percent of annual income for years prior to 1944 and 10 percent for 1944 and subsequent years. These deductible expenses were subtracted from total annual income to obtain net income. All income was considered to be earned. The allowance for earned-income credit is 10 percent of net income. The normal tax and surtax were computed by using the tax rates given in the instructions provided with Internal Revenue Form 1040 and were combined to obtain the total income tax. The defense tax was also added for 1940 and the victory tax for 1943.

TABLE L–9: Average income-tax payments of families, by size of income, 1939–47[1]

Average annual income	Average income-tax payments

[1] Family consisting of husband, wife, and two children.

Distribution of Urban Families by Income

The Bureau of Labor Statistics cooperated[1] in a study of the income distribution of urban families of two or more persons, covering 1935–36, and made two subsequent studies for 1941 and 1944. All information was obtained by personal interview, using a detailed questionnaire. Results of all three surveys are given in table L–10; the size and character of the 1941 and 1944 samples are described in footnotes to this table. Although the samples were small, they were designed to insure the greatest possible efficiency and reliability in yielding national estimates of the distribution of national income. The estimates for 1935–36 were based on a much larger sample, primarily designed to allow study of the effect of various factors on income and expenditures.

A family was defined as a group of persons, usually related, who lived together during a designated period, who contributed to the family income or received a large part of their support from family funds. Relatives of the family head who ordinarily lived with the family but were temporarily away from home (but not living on military reservations) were included as family members. In the 1935–36 survey, sons and daughters living with their parents but paying some amount for board and lodging and not pooling their incomes in the common fund were classified as single individuals rather than as members of the family. In 1941, sons and daughters were more often than not treated as family members, even though they paid for room and board, and, in 1944, it was the usual practice to include them in the family.

Money income was defined in each survey as the sum of all types of money income received by family members during the year: wage and salary earnings (less occupational expenses), entrepreneurial net income or withdrawals, and nonearned income from all sources, exclusive of inheritances, large gifts, and lump-sum insurance settlements. In the 1935–36 survey, however, the portion of inheritances and large cash gifts used for current living expenses was treated as current income. Excluded from net money income (in all three surveys) were gains or losses from the sale of capital assets owned at the beginning of the year and funds obtained through borrowing.

---

[1] The Bureau of Labor Statistics jointly with the Bureau of Home Economics of the United States Department of Agriculture cooperated with The Works Progress Administration and the National Resources Committee in this study.

TABLE L–10: Distribution of urban families of two or more persons, by annual money income, selected periods 1935–44

Money income classes	Percent of total		
	1935-36[1]	1941[2]	1944[3]
All classes	100.0	100.0	100.0
Under $500	11.5	3.7	1.4
$500 and under $1,000	24.7	10.9	5.0
$1,000 and under $1,500	23.7	13.2	5.0
$1,500 and under $2,000	15.9	18.3	8.6
$2,000 and under $3,000	14.7	30.8	22.7
$3,000 and under $5,000	6.2	16.6	37.6
$5,000 and over	3.3	6.5	19.7

[1] Estimate of National Resources Committee, based on the Study of Consumer Purchases, adjusted by the Bureau of Labor Statistics to a money income classification. See Bureau of Labor Statistics Bulletin 822, table 3 (p. 202).

[2] The urban section of the Study of Spending and Saving in Wartime covered 1,300 families and single persons in 62 cities selected to give proper representation to city size groups, region, State, rental levels, racial composition, and proximity to a metropolis. See Bureau of Labor Statistics Bulletin 822, table 1, (p. 68).

[3] The Survey of Prices Paid by Consumers included 1,700 families and single persons in 28 metropolitan districts and 20 cities with populations under 50,000, selected to represent all cities of 2,500 or more, with respect to region, State, and city size. See Monthly Labor Review, February 1946, City Family Composition in Relation to Income, 1941 and 1944, table 2 (p. 178).

Washington 25, D. C. — Price 35 cents

LETTER OF TRANSMITTAL

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., May 21, 1947.

The Secretary of Labor:

I have the honor to transmit herewith a report on the effects of long working hours.

This report was prepared in the Industrial Hazards Division by Max D. Kossoris and Reinfried F. Kohler, assisted by Irving Zeig, Benjamin Minowitz, and Gladys C. Locke. This is one of the Bureau's pioneer studies in the general field of working conditions.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

CASE STUDIES

Page

Nonferrous-metal foundry:

1. Workweek of 60 hours vs. one of 50 hours, no wage incentives; hot and heavy, man-paced floor-mold operations 63
2. Workweek of 60 hours with no wage incentives vs. one of 50 hours with individual wage incentives; floor-mold operations 64
3. Workweek of 58 hours, night shift, with no wage incentives vs. one of 50 hours with individual wage incentives; hot and medium-heavy, man-paced, squeezer-mold operations 65
4. Workweek of 58 hours, day shift, with no wage incentives vs. one of 55 hours with individual wage incentives; squeezer-mold operations 66

Upset-forge plant:

5. Prewar workweek of 52 hours vs. war workweeks of 58 and 52 hours, day shift, individual wage incentives; hot and heavy, man-paced operations 66
6. Prewar workweek of 50 hours vs. war workweeks of 58 and 50 hours, night shift, individual wage incentives; hot and heavy, man-paced operations 69

Gear couplings:

7. Workweek of 40 hours vs. workweeks of 50 and 58 hours, individual wage incentives; medium-heavy, machine-paced machining operations 70

Page

Engine manufacture:

8. Workweeks of 40 hours vs. 48 (6 days) vs. 48 (5 days) vs. 55 (6 days), individual wage incentives; medium-heavy, mostly operator-paced machining operations; ceilings on earnings 73

Welding shop:

9. Workweek of 45 hours vs. one of 58 hours, group wage incentives; fairly hot and heavy, operator-paced operations 74

Metal parts:

10. Comparisons of efficiencies by shift and by sex of workers; light, operator-paced, and automatic-machine operations at hourly schedules varying between 45 and 66 hours; indirect wage incentives 76
11. Workweek of 45 hours vs. one of 55 hours for women, day shift, indirect wage incentives; light, operator-paced machining operations 79
12. Workweek of 45 hours vs. one of 57 hours for women, evening (second) shift, indirect wage incentives; light, operator-paced, machining operations 80
13. Workweek of 45 hours vs. one of 55 hours for women who changed from an evening (second) to a day shift, indirect wage incentives; light, operator-paced machining operations 81
14. Workweek of 45 hours vs. one of 55 hours for women who changed from a night (third) to a day shift, indirect wage incentives; light, operator-paced machining operations 81
15. Workweek of 45 hours vs. one of 57 hours for women who changed from a night (third) to an evening (second) shift, indirect wage incentives; light, operator-paced machining operations 82

Metal bearings:

16. Workweek of 45 hours vs. one of 55 hours, day shift, indirect wage incentives; light, operator-paced machining operations 82
17. Workweek of 45 hours vs. one of 57 hours, night shift, indirect wage incentives; light, operator-paced machining operations 83

Airfield landing mats:

18. Workweek of 58 hours vs. one of 48 hours, group wage incentives; medium-heavy, operator-paced machining and assembling operations 84

Drills and reamers:

19. The effectiveness of Sunday work for workers on light, operator-paced machining operations; individual wage incentives 85

Manufacture of shells:

20. Workweek of 40 hours vs. one of 60 hours, day shift, group wage incentives; medium-heavy, operator-paced machining operations 87
21. Workweek of 40 hours vs. one of 66 hours, night shift, group wage incentives; medium-heavy, operator-paced machining operations 88

Finishing department in a foundry:

22. Workweek of 48 hours vs. one of 55½ hours, no wage incentives; medium-heavy and heavy, operator-paced chipping, grinding, and welding operations 89

Floor-mold department in a foundry:

23. Workweek of 48 hours vs. one of 54 hours, no wage incentives; medium-heavy and heavy, operator-paced operations 90

Metal parts:

24. The effectiveness of Sunday work during a 54-hour week vs. a 58-hour week without Sunday work, indirect wage incentives; light, operator-paced machining operations 91
25. Workweek of 37½ hours vs. one of 58 hours for men, individual wage incentives; light, operator-paced machining operations 92

Page
26. Workweek of 37½ hours vs. one of 54 hours for women, individual wage incentives; light, operator-paced assembling and machining operations .. 93

Piston rings:

27. Irregular overtime vs. a fixed 8-hour daily schedule with occasional Sunday work for men, individual wage incentives; light to medium-heavy, operator-paced machining operations 93
28. The effectiveness of Sunday work for women, individual wage incentives; light, operator-paced machining operations 94

Textile manufacturing machinery:

29. Workweek of 58 hours vs. one of 50 hours, and the effects of reductions in the work force, for men, individual wage incentives; medium-heavy, operator-paced machining operations 96

Air brakes:

30. The effects of changes in hours and improvements in working methods for women, day shift, individual wage incentives; light, operator-paced machining operations 97
31. The effects of changes in hours and improvements in working methods for women, night shift, individual wage incentives; light, operator-paced machining operations 98
32. The effects of changes in hours and improvements in working methods for men, day shift, individual wage incentives; light, operator-paced machining operations 99
33. The effects of changes in hours and improvements in working methods for men, night shift, individual wage incentives; light, operator-paced machining operations 99
34. The effects of changes in hours and improvements in working methods for men, group wage incentives; light, operator-paced assembling and testing operations 100

Dental equipment:

35. Workweek of 54 hours vs. one of 61½ hours, individual wage incentives; light, operator-paced machine and bench operations 100

Manufacture of shells:

36. Six-day week vs. 5-day week for night work or biweekly rotating shifts, individual wage incentives; medium-heavy, operator-paced machining operations 102

ffice filing supplies:

37. Workweeks of 40 hours vs. 48 (6 days) vs. 48 (5½ days) vs. 54 (6 days), group wage incentives; light, operator-paced, hand composition of printing type; men 103
38. Workweeks of 40 hours vs. 48 (6 days) vs. 48 (5½ days) vs. 54 (6 days), group wage incentives; light, operator-paced packing operations; women 105
39. Workweeks of 48 hours (6 days) vs. 48 (5½ days) vs. 54 (6 days), group wage incentives; medium-heavy, operator-paced shipping operations; men and women 106
40. Workweeks of 48 hours (6 days) vs. 48 (5½ days) vs. 54 (6 days), day shift, group wage incentives; light, operator-paced assembling operations 106
41. Workweeks of 48 hours (6 days) vs. 48 (5½ days) vs. 54 (6 days), night shift, group wage incentives; light, operator-paced assembling operations 107
42. Workweeks of 48 hours (6 days) vs. 48 (5½ days) vs. 54 (6 days), group wage incentives; light, operator-paced cutting and packing operations 107

gar manufacture:

43. Workweek of 40 hours vs. one of 44 hours, day shift, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves 108

Page
44. Workweek of 40 hours vs. one of 43½ hours, night shift, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves 110
45. Workweeks of 48 hours vs. 40 and 45 hours, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves 111
46. Workweeks of wartime 45 and 47 hours and postwar 40 hours, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves 112
47. Workweeks of wartime 44½ and 46½ hours and postwar 40 hours, individual wage incentives; light, operator-paced operations in hand-stripping of tobacco leaves 113
48. Workweeks of wartime 44 and 46½ hours and postwar 40 hours, individual wage incentives; light, operator-paced operations in hand-stripping of tobacco leaves 115
49. Workweeks of prewar 40 and 44 hours, wartime 46, 45, and 47½ hours, and postwar 40 hours, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves 116

Candle manufacture:

50. Workweeks of 40, 48, and 53 hours for women, individual wage incentives; light, operator-paced packing operations 118

Nonferrous metal foundry:

51. Workweeks of 40 hours, 44½ hours, 53 hours, and 48 hours, group wage incentives; medium, operator-paced operations 119

Men's trousers:

52. Intermittent schedules ranging from 24 to 48 hours a week for women, individual wage incentives; light, operator-paced machine-sewing operations 121
53. Individual schedules ranging from 20 to 55 hours a week for men, individual wage incentives; medium-heavy, operator-paced pressing operations 123

Men's overcoats:

54. Intermittent schedules ranging from 28 to 52 hours a week for women, individual wage incentives; light, operator-paced sewing operations 124
55. Intermittent schedules ranging from 28 to 52 hours a week for men, individual wage incentives; medium-heavy, operator-paced pressing operations 126

Men's jackets:

56. Intermittent schedules ranging from 28 to 52 hours a week for women, individual wage incentives; light, operator-paced sewing operations 127
57. Intermittent schedules ranging from 28 to 52 hours a week for men, individual wage incentives; medium-heavy, operator-paced pressing operations 129

Men's hats:

58. Workweeks of 48, 40, 46, and 43 hours for women, individual wage incentives; light, operator-paced operations 130

Packaging of biologicals:

59. Workweeks of wartime 48 hours and postwar 40 hours for women, individual wage incentives; light, operator-paced operations 132
60. Workweeks of wartime 48 hours and postwar 40 hours for women, group wage incentives; light, operator-paced operations 133

Packaging of pharmaceuticals:

61. Workweeks of wartime 48 hours and postwar 40 hours for women, individual wage incentives; light, operator-paced operations 134
62. Workweeks of wartime 48 hours and postwar 40 hours for women, group wage incentives; light, operator-paced operations 135

Page

Packaging of cough drops:

63. Workweeks of wartime 48 hours and postwar 40 hours for women, individual wage incentives; light, operator-paced operations 136

Metal parts:

64. Workweeks of prewar 40 and 55 hours, wartime 58 and 50 hours, postwar 45 to 50 hours for men, individual wage incentives; heavy, operator-paced machining operations 137
65. Workweeks of wartime 58, 55, and 50 hours and postwar 48 hours for men, individual wage incentives; heavy, operator-paced machining operations 140

Coil winding:

66. Workweeks of wartime 45 and 50 hours and postwar 45 hours for women, individual wage incentives; light, operator-paced manual and machining operations 141

Machine shop:

67. Workweeks of prewar 40 and 55 hours, wartime 62 and 55 hours, and postwar 40 to 48 hours for men, individual wage incentives; medium-heavy, operator-paced machining operations 142

Metal parts:

68. Workweeks of prewar 36, 43, and 54 hours, and wartime 60 and 52 hours for men, individual wage incentives; medium-heavy, semi-automatic operations 144

Molded rubber specialties:

69. Workweeks of 40 and 48 hours, in prewar, war, and postwar periods, for men, day shift, individual wage incentives; medium-heavy, operator-paced press-molding operations 147
70. Workweeks of 40 and 48 hours in prewar, war, and postwar periods, for men, evening shift, individual wage incentives; medium-heavy, operator-paced press-molding operations 149
71. Workweeks of 40 and 48 hours in prewar, war, and postwar periods, for men, night shift, individual wage incentives; medium-heavy, operator-paced press-molding operations 150
72. Workweeks of 40, 48, and 54 hours in prewar, war, and postwar periods, for men, day shift, individual wage incentives; medium-heavy, operator-paced operations 152
73. Workweeks of 40 and 48 hours in prewar, war, and postwar periods, for women, day shift, individual wage incentives; light, operator-paced trimming and finishing operations 153

Rubber hose:

74. Workweeks of 40, 48, and 57 hours in prewar, war, and postwar periods, for men, day shift, individual wage incentives; light to medium-heavy, operator-paced operations 154

Aircraft manufacture:

75. Absenteeism during 58-hour workweeks of 5 and 6 days in a plant manufacturing aircraft; plant-wide bonus 156

Metal parts:

76. Comparison of absenteeism by sex and shift; light, operator-paced machining and assembling operations; no wage incentives 157

Generator manufacture:

77. Daily patterns of absenteeism for men and women during 5- and 6-day workweeks, individual wage incentives 158

Piston rings:

78. Wartime workweek of 48 hours vs. postwar workweek of 35 hours, individual wage incentives; light, machine-paced machining operations 159

Hours of Work and Output

Introduction and Summary

"What constitutes the optimum workweek?" is a question frequently asked by management. Presumably, what is meant by this question is: "What schedule of working hours will give me the best results?"

The answer supplied by this survey is that there is no such thing as an optimum workweek. Workers perform differently under the same hours because of a variety of factors: the incentive to produce; the physical demands which the job makes upon them; the degree to which they control the work pace; the conditions under which they work; whether they work on day, evening, or night shift; whether or not, and how frequently, shifts are rotated; and—less tangibly—whether their relations with management are cordial or otherwise.

This study shows, furthermore, that the way in which a longer work schedule is achieved has a decided bearing on the results. Thus, a 55-hour schedule may be achieved by working 5 days at 10 hours and 1 day at 5, or 6 days at 9 hours, or 5 days at 11 hours, or 7 days at 8 hours. The results in terms of efficiency, absenteeism, and output may well be different for each of these schedules, even though the total hours worked per week are identical, or nearly so. Obviously, too, the labor cost per unit of output achieved may vary considerably under these various patterns.

Generally speaking, the study indicates that, everything else being equal, the 8-hour day and 40-hour week are best in terms of efficiency and absenteeism and that higher levels of hours are less satisfactory. The results of the same increases in hours may vary widely according to the physical exertion required and the degree of control which the worker has over the job. Where the controlling factor is the pace of the machine, and if the worker can retard or speed up production only during relatively minor intervals of time—such as taking 5 minutes to take off a completed part and place a part to be processed on the machine, while the machine operation may take a half hour or more—the controlling factor is the machine. If, on the other hand, the machine works as fast or faster than the operator, then efficiency definitely depends on the exertion of the worker. It is under these types of conditions, or the similar ones in which no machines are involved at all, that the fatiguing factor of long hours comes into play.

In the 78 case studies presented here, covering 2,445 men and 1,060 women workers in 34 plants in a considerable variety of industries, it was generally found that the longer schedules resulted in larger output. In only a few instances were lengthened hours so long that no increase in output resulted. At times, the increment of additional output hardly warranted the ime expended and the cost involved. As a rule, however, the longer hours yielded higher output—but at a regressive rate. As hours went up, the proportionate return decreased, and unit labor cost increased. But, during the war, cost was no consideration, and output was essential at any cost. During a peacetime economy, however, the emphasis is on efficient, low-cost operation. Then the relative costs of production at various daily and weekly schedules of hours are very important.

The survey does not include any studies—except in a few clothing plants—on the effects of hours less than 40 per week. It is not possible, therefore, to make any suggestions as to the relative value of shorter work schedules. It should be quite obvious, however, that the shorter the workweek, the less any worker can afford to absent himself. The longer the workweek, the greater is the pressure for some time out to attend to personal matters—shopping, seeing the dentist or physician, attending to family matters, or just a day off for additional rest—and the less is the urgency not to lose a day's pay. It is literally true that workers cannot afford to be ill when working shorter hours and that they frequently come to work in spite of great discomfort.

Much was said and written about absenteeism during the war. Some managements attributed the higher absenteeism during the longer hours to the fatigue engendered by the longer work schedules. In addition, they realized that the long hours imposed considerable hardships on workers, particularly women, who had duties outside the plant. Others thought workers were earning so much money that they didn't know what to do with it and consequently did not see the necessity of working a full schedule. At times, this explanation appeared to have considerable basis in fact. For instance, the labor in one large foundry had been recruited from the South and received much higher hourly pay than ever before. Absenteeism ran high—presumably because this type of labor had not yet raised its standard of living to a point high enough to require the pay for a full week's work. But, whatever the reason, one fact stands out clearly in the survey: the longer the hours, the more scheduled worktime lost through absenteeism.

As a rule, the absenteeism loss of women exceeded that of men. That was generally true at every level of hours. It is known that women lose more time than men through illness, and that the periodic menstrual cycle has a bearing on this problem. When home responsibilities and the care of a household or children are added, it is not difficult to find additional explanations for this difference.

Injuries also increased as hours increased, not only in absolute numbers, but also in the rate of incidence. In most of the observed instances, the number of injuries per million hours worked was very much higher at the longer hours. Sometimes an effective accident-prevention program managed to hold the rates down to about the same level. At other times the rates went up in spite of everything that was done.

Briefly, the findings for the various types of daily and weekly schedules of hours observed may be summarized as follows:

. *The 5-day workweek—with increases in daily hours*

(a) Men at moderately heavy, but essentially machine-paced work, we early as efficient during a 10-hour day as they had been during an 8-hou ay. Absenteeism remained at about the same level.

(b) Women at light and operator-paced work were 4 to 5 percent less effi- ient during a 9- or 9½-hour day than during an 8-hour day. There was, owever, no marked change in absenteeism.

. *Adding a sixth day—with daily hours constant*

(a) Men at moderately heavy work performed about as well during the -day week as they had during the 5-day week in terms of efficiency and ab- enteeism. As a rule, daily hours were held at 8.

(b) Women at light work were about as efficient during a 6-day week at hours per day as they had been during a 5-day schedule. But absenteeism creased substantially.

(c) For both men and women, output increased substantially in the same roportion as hours.

Eliminating the sixth day—without changing daily hours

(a) Men at heavy or moderately heavy work were 5 to 10 percent more ficient during a 10-hour day, but with the sixth day eliminated. Their effi- ency was 13 to 15 percent better during an 8-hour daily schedule. There as little difference in absenteeism.

(b) Women at light work were about 7 or 8 percent more efficient during e 5-day week, with daily hours at 8 under both weekly schedules. Absen- eism tended to be less during the 5-day week.

(c) The reason for the differences in efficiency and absenteeism when add- g a sixth day and when eliminating the sixth day appears to lie in two fac- rs: (1) When hours are not too long for the physical demands involved, the ice characteristic of the 5-day week can be maintained fairly well during e 6-day week. Absenteeism is held down fairly well because of the overtime iy for the sixth day. (2) When the sixth day is eliminated, workers try to coup some of the lost earnings by speeding up during the 5-day week.

Any comparison of the 5- and 6-day schedules, with daily hours usually ld to 8, must take into account whether the sixth day is to be added or taken vay. The results are quite different.

Adding a sixth day—and increasing daily hours

(a) For both men and women at any type of work except work that was tirely automatic, the increasing of daily hours from 8 to 9 or 10 and adding sixth day, resulted in substantially poorer performance. Particularly was is true when daily hours were raised to 10 and weekly hours to 60 or more. osenteeism increased substantially for workers of both sexes, and particu- ly for women.

(b) In comparison with the pattern of the 6-day week without an increase daily hours, the 6-day schedule with increases in daily hours to 9 or 10

s decidedly less desirable. In some instances the increases in daily hours peared to have been a complete waste.

. Changing from 6 days to 5½—but increasing daily hours

(a) For women, this usually involved working 8¾ hours for 5 days and 4 hours on Saturday. Efficiency was better in every instance during the 5½-day week.

The difference in absenteeism was obscured by opposite results. Some workers found it possible to take off the one-half day Saturday because they had earned more per hour during the other days of the week. Other workers, who had the one-half day off on Saturday, found it possible to work the other half, rather than take off the entire day to attend to other needs.

(b) For men, the number of cases observed was too few to warrant any conclusions. From results in other patterns, one may hazard the guess that efficiency would rise during the 5½-day week, but that there would be little difference in absenteeism.

6. The 6-day week—with increases in daily hours

When daily hours were increased during the 6-day week, usually from 8 hours to 9 or 10, with increases in weekly hours from 48 to 54 or 60, efficiency was substantially poorer during the longer workweek for both men and women at all types of work. Absenteeism was considerably higher. Generally, it took about 3 hours of work to produce 2 additional hours of output when hours exceeded 48 per week.

7. The 6-day week—with decreases in daily hours

(a) At moderately heavy or heavy work, the efficiency of men was substantially better during the 8-hour day than it had been during the 9- and 10-hour day. Only 1 hour's output was lost for every 2 hours taken off the schedule.

(b) No observations can be presented for women workers.

8. The 7-day week—Sunday work

(a) Given a regular daily 8-hour schedule, workers performed better when no Sundays were worked. After protracted periods of 7 days of work per week, workers actually produced as much, or more, in 6 days as they formerly had in 7 days. In the cases studied, it was literally true that Sunday work meant 8 days' pay for 6 days' output.

Absenteeism was high on Sunday. Men who worked on Sunday frequently took some weekday off.

(b) Occasional, but regularly scheduled Sunday work, appears to have been better than irregular overtime during other days of the week.

9. The pattern of daily efficiencies

The daily efficiency pattern does not emerge very clearly as daily and weekly hours are increased. The one which appears to fit observations most closely is about as follows:

(a) During a 40-hour week, with 5 days at 8 hours, efficiency builds up o a peak on Wednesday or Thursday, with a slight drop on the remaining ays of the week.

(b) As hours are increased to 10 per day, for a total of 50 per week, the nidweek peak disappears and the whole week's efficiency level remains fairly onstant, at about the Monday level.

(c) When a sixth day is added, at about 8 hours, the daily efficiency level tays flat—but drops to a level lower than that which had prevailed during he 5-day week at 10 hours per day.

0. The pattern for daily absenteeism as workdays exceed 5 a week

(a) There appears to be no constant pattern for the 5-day week.

(b) When the week consists of 6 workdays, absenteeism for both men and vomen is highest on Saturday. The absenteeism rate is particularly high if aily hours are 9 or 10, rather than 8.

(c) Saturday absenteeism is particularly high for women. Their absenteesm rates, however, are higher than those for men on all other days of the veek as well.

(d) For the night shift, absenteeism is highest on the first night of the veek, if work begins Sunday night. There is, however, no week-end peak.

1. Work injuries

Work injuries increase disproportionately as daily hours are raised above and weekly hours are raised above 40. The frequency rate of work injuries ises even more sharply as weekly hours are raised to 54 or more.

2. Output

With few exceptions, the longer hours resulted in greater output than that roduced during the shorter schedules. As a rule, however, the increase in utput fell considerably short of the increase in hours. For hours above 8 per ay and 48 per week, it usually took 3 hours of work to produce two addiional hours of output when work was light. When the work was heavy, it ook about 2 more hours of work to produce 1 hour of additional output.

3. Work without wage incentive

The foregoing observations apply primarily to workers at piecework or nder some fairly direct form of wage incentive. When work was done at day ates, without any wage incentive, the workers were as productive at longer chedules as they had been at shorter schedules. The work pace remained ssentially the same.

It must be added, however, that long schedules had no adverse effect on vorkers operating under wage incentives if their pace during the shorter work chedule was moderate. Under such conditions they not only could maintain heir efficiency at the longer hours, but were even capable of improving it. It s likely however, that this would not hold true for weekly hours above 60, ecause of the cumulative effects of fatigue.

CHAPTER I.—The Objective

The prevalence of the 8-hour day and 40-hour week in the manufacturing plants in the United States makes it difficult to determine the effects of longer schedules of daily and weekly hours over a protracted period of time. Except in cases of unusual emergency, the general objection to overtime penalties usually holds hours to these accepted levels.

During the war, however, cost was no barrier. The pressure for maximum output, coupled with the withdrawal of millions of men from the labor force for the armed services, created a tremendous labor problem which was solved in one, and usually both, of two ways: (1) by expanding the labor force by drawing on whatever reserves were available, and (2) by working longer hours. The considerable variety of hourly patterns worked during the war afforded the unusual opportunity to observe their results.

English studies during both World Wars have indicated the folly of working excessively long hours, such as 70 or 80 per week. Immediately after Dunkirk, efficiency dropped sharply and absenteeism increased alarmingly after only a period of weeks, in spite of the drastic emergency. During brief spurts, it was possible to draw on the reserve strength of workers and to obtain greatly increased output. Over extended periods, however, it was found that the output at the high levels of hours might be no higher, and sometimes was actually lower, than it had been at the shorter hours. Efficiency declined, absenteeism and injuries increased, and the inevitable result was an output level which fell far short of the corresponding increase in hours.

Workweeks of 70 and 80 hours were infrequent in this country, even during the worst manpower shortages during the war. But weeks up to 60 hours were not uncommon, and workweeks of 54 and 58 hours were scheduled quite generally.

The simplest way of increasing weekly hours was to retain the 5-day week, but to lengthen daily hours to 9, 10, or 11. The next step was to add a sixth day. Subsequently a seventh day might be added. In other plants, the 8-hour day was maintained at first, and the workweek was lengthened by the addition of a sixth day, frequently at 8 hours. As this schedule proved inadequate, daily hours were increased to 9 or 10, with a shorter schedule on Saturday, usually varying from 4 to 8 hours. Obviously, there was no uniform pattern. Each plant tried to adjust itself to a schedule in keeping with its labor supply, production facilities, and backlog of orders.

As a rule, the limiting factor in any consideration of the effectiveness of varying work schedules is that of fatigue. The human being is not a machine and cannot keep on working with the same efficiency hour after hour. His effectiveness will vary with the physical demands which his job makes on him. He will tire faster at some types of work than at others. Where the demands on him are greater than he can bear, he either breaks down or he lows down so as to stretch his available energy over a longer working chedule.

This study, however, is not a clinical or physiological study of fatigue. The precise character of fatigue and the changes in muscular function or nervous reaction to stimuli that are involved must be left to the medical profession. This study is an attempt to determine, from industry's own experience, he ways in which this fatigue manifests itself as a practical factor limiting production—by lowering efficiency, increasing absenteeism, increasing the ncidence of work injuries, and ultimately, by effecting the level of total output. As the objective of the longer work schedule is to increase output, the criterion of the effectiveness of any one schedule of hours is the output level which can be maintained consistently at that level of hours.

The task of finding plants suitable for study was difficult. Out of more than 800 plants visited, only about 50 met the necessary qualifications. The majority of the 800 plants were willing to cooperate and were interested in finding out what their experiences showed when subjected to objective statistical measurements. But most of the plants visited could not be included in the urvey for a variety of reasons.

In order to permit the effects of various schedules of hours to emerge clearly, it was necessary to rule out all other variables. A plant, therefore, could not be studied if, during the various periods to be surveyed, hours were not maintained consistently at fairly fixed and definite schedules. During hese periods, the operations performed by the workers to be studied had to emain essentially unchanged, and the number of identical workers involved had to be reasonably large. Obviously, if the nature of the work changed materially and if the composition of the work force was changed, factors other than hours could be responsible for the changes observed. Furthermore, output had to be measurable, and records had to be available on hours, output, and absenteeism for the group of workers to be studied.

Most frequently, the absence of records was the stumbling block. It was amazing to find hundreds of plants that had no records of output, except perhaps for entire departments, and that kept no records on absenteeism or work injuries. The plants which most frequently lent themselves to the survey were plants which used some method of wage incentive and consequently had to keep some record of output and earnings for individual workers. But even in these plants, the only record frequently available was one of pay-roll earnings.

The requirements of the survey demanded further that weekly working schedules must have been altered substantially, and that the contrasting schedules must have been in effect long enough—preferably at least 6 months to a year—to permit a valid comparison of worker performance for at least two distinct levels of hours. It usually was necessary to rule out transitional periods of 1 to 4 months, during which work schedules frequently fluctuated, for the effectiveness of the new schedule to emerge clearly.

In the presentation of the completed case studies, the objective was to state the findings simply; shorn, as much as possible, of statistical verbiage and concepts. In contrast with the fairly comprehensive preliminary publications of the first 12 plant studies,[1] those included in this volume have been reduced to statements of essentials only. Each group of workers studied is presented as a separate case study; the industrial operations include plants engaged in the production of castings, forgings, radios, airplanes, industrial machinery, motors, shells, dental equipment, rubber products, cigars, clothing, hats, candles, and drugs.

No account was taken of sociological factors which undoubtedly influenced the effectiveness of workers in many ways. No attempt, for example, was made to evaluate the needs for changes in store hours so as to facilitate shopping for the industrially employed women with household duties, or the adequacy of transportation and housing facilities, or the myriad other factors which congested wartime conditions entailed. The objectives of this survey were more limited: to measure objectively the effects of working hours on the performances of workers and to determine how these schedules compared in obtaining the goal of increased output.

In the discussion of each work schedule, findings will be shown separately for heavy, moderately heavy, and light operations. In the first category are operations such as are found in forge shops and foundries, and in which the work normally involves the handling of heavy materials. The category of light work involves, as a rule, the manual handling of materials up to about 5 pounds, or the mechanical handling of somewhat heavier objects. The moderately heavy group falls somewhere between these two. Th purpose of this classification is to indicate, in a general way, the type of physical demands made upon the workers.

Findings are classified also as to pace control. In some operations, such as those involving automatic or semi-automatic screw machines, the pace was entirely controlled by the machine. In other types of machine operations the pace was essentially controlled by the machine, but the worker could exert some control by means of the speed with which he removed a processed part from the machine and replaced it with another to be processed. As a rule, operations classified as machine-paced involved a cycle in which the time interval subject to operator control was quite small as compared with the interval required by the machine. The third category is the operator-paced operation, in which the speed of the operation was controlled either entirely or primarily by the efforts of the operators.

---

[1] Studies of the Effects of Long Working Hours, Part 1 and Part 2, Bulletins 791 and 791 A, U. S. Bureau of Labor Statistics, 1944.

CHAPTER II.—5-Day Week

Only 2 of the 13 case studies falling into this pattern of schedules involved nen. Both of these studies were made in the same department of a plant nanufacturing gear couplings. The 39 men in case study 7 (a) were a group of operators who had been at this work for many years. The 50 men in case tudy 7 (b) were men hired during the war. They were experienced mechancs, but not as experienced on this particular job as the men in group 7 (a).[2] n both studies, the men were engaged in a variety of machining operations n metal working machines. The work was machine-paced and moderately eavy.

As table 1 shows, a change from 8 hours per day to 10, but with the retenion of the 5-day week, resulted in a drop of 4 percent in hourly efficiency, ven though the time interval subject to operator control was small. Scheduled work time lost because of absenteeism rose to 7 percent for each group, lthough the time loss for the group of "new" employees (7 (b)) was subtantially above that of the old employees (7 (a)) during the 40-hour week.

ABLE 1.—*Effects of changes in daily and weekly hours on efficiency and absenteeism during the 5-day week*

Case study and type of work	Number of workers	Sex	Changes in hours				Efficiency percent change	Absenteeism rate [1]	
			Daily		Weekly				
			From	To	From	To		From	To
achine-controlled pace:									
7a — Moderately heavy......	39	Male	8	10	40	50	—4.0	2.7	7.0
7b — Moderately heavy......	50	....do	8	10	40	50	—4.0	5.4	7.0
perator-controlled pace:									
45a — Light........	13	Female	8	9	40	45	—5.4	(²)	(²)
45b — Light........	13	....do	8	9½	40	48	—16.2	(²)	(²)
46 — Light.........	24	....do	8	9½	40	46½	—1.0	3.2	4.6
47a — Light........	10	....do	9	9½	44½	46½	—4.0	2.8	2.8
47b — Light........	10	....do	8	9½	40	46½	—6.3	5.4	3.1
48a — Light........	21	....do	8	9½	40	46½	—2.6	3.1	2.1

49b — Light........	13	....do	8	9½	40	47½	—1.3	5.5	4.3
58 — Light........,	28	....do	8	8 or 9	40	43	+1.3	8.4	16.7
66 — Light.........	9	....do	9	10	45	50	+1.2	5.3	5.8

[1] Percentage of scheduled worktime lost.

[2] Not determined.

The other 11 studies all involved women operators engaged in light work. Reference to the case studies themselves will show them as occupied most frequently in the stripping of tobacco leaves. In almost every study, the pace was fast and entirely controlled by the operators, who worked at piece rates.

In only one of these studies did weekly hours go as high as 50. As a rule they remained below 48. There were two reasons for this: (1) women frequently were barred from longer hours by State legislation, and it was necessary to obtain special permission to exceed the established limits; and (2), women frequently objected to working longer hours because of home duties.

---

[2] To facilitate comparisons, certain individual case studies have been broken down into groups (a) and (b), in both text and tables.

In all but two of the case studies (58 and 66), the longer daily hours resulted in decreases in efficiency, ranging from as low as 1.0 percent to as high as 16.2 percent. In the two instances in which hourly efficiency increased, the increases were slight—1.3 and 1.2 percent, respectively. In case study 58, however, the absenteeism loss jumped from 8.4 percent of the scheduled employee-hours to 16.7 percent.

As a general proposition, the changes in absenteeism were minor. It is important to bear in mind that these operators were free from work on Saturday and Sunday, and that the women had the opportunity to do much of their shopping and household chores over the 2-day week end.

In every instance but one, the increased hours resulted in increased output. In that one (case study 58) the sharp increase in absenteeism overbalanced the slight increase in efficiency, so that a 43-hour week actually resulted in a somewhat lower output than obtained under the 40-hour week. Reference to table 2, however, indicates that in all cases but 2 (49 (b) and 66), the increase in output was not in direct proportion to the additional hours worked.

TABLE 2.—*Effects of changes in weekly hours on output during the 5-day week*

Case study and type of work	Weekly hours changed —		Percent change in —		Output-input ratio
	From	To	Hours	Output	
Machine-controlled pace:					
7a — Moderately heavy	40	50	+25.0	+23.5	0.9
7b — Moderately heavy	40	50	+25.0	+18.0	.7
Operator-controlled pace:					
45a — Light	40	45	+12.5	+6.4	.5
45b — Light	40	48	+20.0	+.6	(1)
46 — Light	40	46½	+16.3	+13.3	.7
47a — Light	44½	46½	+4.5	+.2	.1
47b — Light	40	46½	+16.3	+11.8	.7
48a — Light	40	46½	+16.3	+14.2	.9
48b — Light	40	44	+10.0	+6.7	.7
49a — Light	40	44	+10.0	+7.9	.8
49b — Light	40	47½	+18.8	+18.6	1.0
58 — Light	40	43	+7.5	—1.1	—.1
66 — Light	45	50	+11.1	+11.8	1.1

(1) Less than 0.1.

In the case of the men in studies 7 (a) and 7 (b), a 25-percent increase in hours resulted in 23.5 and 18 percent of increased output. As the output-input ratios show, for each additional workhour 0.9 and 0.7 of the hourly output at the lower level of hours resulted. In both of these studies, however, operations were machine-paced, so that the hours of actual machine time corresponded fairly closely to the actual working time.

All of the other studies show output depending primarily on the speed and endurance of the operators. In general, the data indicate that every 3 additional hours of work per week resulted in an equivalent output increase of only 2 hours. The ratio of output hours gained to the additional hours worked is 0.7 or less in case studies 45 (a), 45 (b), 46, 47 (a), 47 (b), 48 (b), and 58. In case 45 (b), the output of the 48-hour week was barely better than it had been under the 40-hour week—apparently 7½ hours were completely wasted. Similarly, in 47 (a), the 44½-hour week was as productive as the 46½-hour week.

The proportionate increase in output observed in case study 49 (b) reflects a persistent drive by management for increased output. In case study 66, the better ratio seems to be due primarily to the increase of 1.2 percent in efficiency at the light and repetitive task of winding small coils. The pace of these operators, however, was more moderate and could be maintained more easily.

It may be concluded from these results that, for women, at light, operator-paced operations, the effect of lengthening daily hours from 8 to 9 or 9½, and weekly hours from 40 to 46 or 47, is a drop in efficiency of 4 to 4½ percent. Except for one extreme case, the absenteeism loss was not affected materially.

Case study 7 for men at moderately heavy work (groups 7 (a) and 7 (b)), indicates that where the work pace is controlled by the machine, thus affording the operator some brief rest periods while waiting for the machine to perform its operation—for example, an automatic multiple-drill press—the increase in output is more nearly proportional to the increase in hours.

CHAPTER III.—5-Day Week vs. 6-Day Week

A.—Increasing workdays from 5 to 6; no change in daily hours

Another way of increasing weekly hours was to hold daily hours constant, but to add a sixth day to the workweek.

This method was observed in the 15 studies enumerated in table 3. In 8 of these, the work was moderately heavy, and, except for case study 7, usually involved a change from 40 hours per week to 48. In case study 7, in both groups (a) and (b), the change was from a 50-hour week to one of 58. In each instance, the group studied was composed of men.

The effects on efficiency of this lengthening in weekly hours in the moderately heavy work groups were nearly evenly divided: in three instances the addition of the sixth day resulted in decreases of efficiency, and in five, it resulted in increases. The changes were not markedly large in either group, and it may be concluded that the addition of a sixth day without increasing daily hours had no adverse effect on efficiency.

In most of these cases, the change in the percent of scheduled worktime lost because of absenteeism did not vary appreciably. The reduction in study 7 (a) from a time-loss rate of 7.0 percent under the 5-day week to 4.5 percent under the 6-day week reflects the efforts of a labor-management committee to reduce absenteeism. The efforts of this committee appear to have been less effective on the more recently hired workers in the same department—their rate increased from 7.0 percent to 8.1 percent.

Of the seven studies for light work shown in table 3, five involved women, and one, an increase in weekly hours from 50 to 58. The other six studies reflect the changes subsequent to the introduction of Saturday work, but with daily hours maintained at 8.

As table 3 shows, the addition of the sixth day had no adverse effect on efficiency in the light-work groups, even though all of it was operator-paced. Case studies 73 (a) and 73 (b) reflect the experiences of groups whose pace was moderate, as was true of case 74 in the table. It seems reasonable to assume that these groups responded to the wartime urgency as well as the chance to increase their overtime earnings by increasing their work pace.

It is to be noted, however, that in every instance the shift to a 6-day week resulted in marked increases in absenteeism for the female operators. The time-loss percentage was doubled and more than quadrupled in case studies 73 (a) and 73 (b), and more than doubled in 38. In case study 58, it rose from 8.4 to 10.3. As a rule, the absenteeism loss for women was higher than that for men under both the 5-day and 6-day weeks.

The composite effects of changes in efficiency and changes in absenteeism are reflected in the output changes shown in table 4.

In every instance, the longer workweek resulted in increased production.

TABLE 3.—*Effects on efficiency and absenteeism of increasing workdays from 5 to 6 per week, without changes in daily hours*

Case study and type of work	Number of workers	Sex	Daily hours	Weekly hours changed —		Efficiency percent change	Absenteeism rate [2]	
				From	To [1]		From	To
Machine-controlled pace:								
7a — Moderately heavy..	39	Male	10	50	58	—2.1	7.0	4.5
7b — Moderately heavy..	50	....do	10	50	58	—1.0	7.0	8.1
8 — Moderately heavy...	700	....do	8	40	48	+1.0	1.8	(3)
Operator-controlled pace:								
51 — Moderately heavy...	32	....do	8	40	44½	—1.9	1.2	4.2
69 — Moderately heavy...	21	....do	8	40	48	+3.5	.7	1.7
70 — Moderately heavy...	8	....do	8	40	48	+1.6	1.1	1.4
71 — Moderately heavy...	10	....do	8	40	48	+1.9	1.7	2.8
74 — Moderately heavy...	14	....do	8	40	48	+3.9	3.0	4.6
31 — Light..............	10	Female	10	50	58	+ .2	6.8	7.7
37 — Light..............	9	Male	8	40	48	+1.4	1.4	.5
38 — Light..............	8	Female	8	40	48	— .4	3.0	6.8
58 — Light..............	28	. . .do	8	40	46	—1.6	8.4	10.3
72 — Light..............	13	Male	8	40	48	+ .8	1.0	1.7
73a — Light.............	9	Female	8	40	48	+1.2	2.0	4.7
73b — Light.............	9	....do	8	40	48	+7.3	2.0	9.2

[1] Where weekly hours are less than 6 times daily hours, shorter hours were worked on Saturday.

[2] Percentage of scheduled worktime lost.

[3] Not determined.

It is also apparent that the higher absenteeism rates were offset by the greater efficiencies, so that total output increased in about the same ratio as did hours. The instances that show serious deviation from this conclusion are studies 7 (a) and 7 (b), 38, 51, and 58.

Cases 7 (a) and 7 (b) differed from most of the other case studies because the regular daily hours were 10. In nearly every other case, daily hours were 8. It is significant that with a 10-hour day, only about 2 hours' output was realized for every additional 3 hours worked above 50, even though the pace at these operations was controlled by machines.

In case study 51, the increase in hours was from 40 to 44½, accomplished by introducing a 4½-hour Saturday. The additional Saturday half day resulted in an increase in total output equivalent to the work of 2⅓ additional hours. As a result, about half the Saturday hours were nonproductive.

In case study 38, the important factor was the increase in absenteeism during the 6-day week for the female workers. And in case study 58, both lower efficiency and higher absenteeism were involved.

The proportional increase in output in case study 31 requires some comment. Here, it will be noted, the 10-hour-day schedule prevailed. But contrary to the experience in case study 7, the female operators maintained the same efficiency during the 58-hour week as they had during the 50-hour week, although absenteeism increased slightly. The reason for the good performance during the longer workweek was better management. During the 58-hour week, materials were taken to and from the machines by other workers, thus enabling the machine operators to spend all their time at the machines. During the 50-hour week, the operators had to move these materials, meanwhile letting their machines remain idle. It is doubtful whether the same favorable result would have been obtained under the longer hours had this change not been introduced. As it was, the managerial change

TABLE 4.—*Effects on output of changes in weekly hours by increasing workdays from 5 to 6, holding daily hours constant*

Case study and type of work	Weekly hours changed —		Percent change in —		Output-input ratio
	From	To	Weekly hours	Output	
Machine-controlled pace:

73a — Light	40	48	+20.0	+17.9	.9
73b — Light	40	48	+20.0	+19.3	1.0

permitted as good a performance during the 6-day week, at 10 hours per day, as had obtained during the 5-day week.

For all other studies shown in table 4, output during the longer workweek increased directly with the increase in weekly hours. In some instances this could be attributed to the stimulus of the war effort. In others, it appeared that the constant building up of a backlog of orders stimulated workers to greater effort. Observation also indicated that in a number of instances the operator pace was only moderately fast, so that the pace could be increased without introducing much of an element of fatigue.

On the whole, it may be concluded that these studies indicate that the addition of a sixth day had no disadvantageous effect on output, provided daily hours were held to 8 per day.

B.—Decreasing workdays from 6 to 5; no change in daily hours

The difference between the 5- and 6-day week, with daily hours constant, can be measured not only in cases in which the sixth day was added, but also in cases in which the sixth day was eliminated.

It was pointed out in the preceding section that, for the 8-hour day at least, the addition of the sixth day had no appreciable adverse effects on efficiency and absenteeism loss. It would be reasonable to presume, therefore, that the elimination of the sixth day would not affect these factors either.

That exactly the reverse is true is demonstrated by tables 5 and 6. As a general rule, the elimination of the sixth day increased efficiency considerably during the shorter workweek.

The single exception to this rule is case study 29. Here, however, the reduction in weekly hours was part of a general retrenchment program, from an expanded wartime to a more modest peacetime scheme of operation, which involved lay-offs for a considerable portion of the work force. The slowing down during the shorter workweek may fairly be ascribed to a slowing down because of this factor rather than to the change in hours.

TABLE 5.—*Effects on efficiency and absenteeism of decreasing workdays from 6 to 5 per week, without changes in daily hours*

[1] Where weekly hours are not 6 times daily hours, shorter hours were worked on Saturday.

[2] Percentage of scheduled worktime lost.

[3] Not determined.

In most instances involving heavy or moderately heavy work, the 10-hour day was retained for male operators under the shorter workweek. If case study 29 is disregarded, the dropping off of a full day on Saturday, usually an 8-hour day, resulted in efficiency increases ranging from 4.9 percent to 11.2 percent for men working under wage incentives. In case study 1, the pace of the 45 men in a foundry, working without a wage incentive, was about the same under both schedules.

Where the workday was only 8 hours the results were nearly as striking. Elimination of the sixth day increased hourly output, i. e., efficiency, by 12.4 percent in case study 69 and 16.1 percent in case study 70.

Just as there was little change in the absenteeism rate for men when the sixth day was added, so there was little change in absenteeism when the sixth day was removed. As will be pointed out later, this was not the case for women.

With one exception, the light operations observed in this change of work pattern involved women. As a rule, hours were reduced from 48 to 40 with the retention of the 8-hour day. In every instance efficiency was better under the shorter schedule, the improvements ranging from 1.5 percent to 12.0 percent.

Not only were the absenteeism losses for women greater than those for men under either pattern of the workweek, they also indicated opposite trends. In cases 58 (a) and 58 (b), the percentage of time lost under the shorter schedule was alarmingly high—16.7 percent, and more than half again as high as under the longer schedule. In case study 59, it rose from 12.1 to 15.2 percent. In case 63, it rose from 10.4 to 12.4 percent, and in 62, from 6.4 to 9.6 percent. As the shorter schedules usually came after VE-day, it is possible that there was a general relaxation and less emphasis on good attendance. It may be observed also that many of these workers had no intention of continuing work in the plants indefinitely. For many of them, VE-day meant impending marriage and the setting up of households. For married women, it frequently indicated the resumption of household duties. These considerations obviously do not apply to men.

Table 6 provides the comparison between the additional hours worked on the sixth day and the resulting additional output. So as to provide a direct comparison with table 4, the computations in this table are shown with the shorter schedules of hours as a base—i.e., as though the longer schedule had followed the shorter schedule. A few studies shown in table 5 are omitted because output could not be computed because of the lack of essential data.

In case study 6, the 16 men at hot and heavy forge work turned out as much at 50 hours as they had at 58 hours. In fact, operations at 58 hours were discontinued when it was realized that the longer work schedule was no more productive than the shorter one had been. The data indicate that the output level might even have gone lower had the change not been made. However, the 10-hour day was maintained. It was not possible, therefore, to determine whether a shorter workday might not have proved as effective as the 10-hour day.

TABLE 6.—*Effects on output of changes in weekly hours by increasing workdays from 5 to 6, holding daily hours constant*

[Pace controlled by operator]

Case study and type of work	Weekly hours [1] changed —		Percent change in —		Output-input ratio

61 — Light	40	48	+20.0	+13.9	.7
62 — Light	40	48	+20.0	+22.4	1.1
63 — Light	40	48	+20.0	+13.8	.7

[1] For ease of comparison with table 4, percentage changes in hours and output have been computed from the lower level of hours.

In case study 3, the output level at 58 hours at moderately heavy work in a foundry was actually lower by 3.2 percent than that for 50 hours.

The reason why performance at 58 hours was better in case study 29 has been given. In only one other case, 58, was performance superior during the longer workweek of 46 to 48 hours than during the 5-day week of 43 hours. The 5-day week, however, involved irregular overtime and included, on the average, 3 days at 9 hours. In both instances a 6-day week at regular hours seems to have been superior to a 5-day week involving overtime.

The group of men in case study 1 were on day work. They retained their pace—which was not fast—under either schedule.

In every other case, the higher efficiency during the 5-day week was sufficiently better to offset from one-third to one-half of the additional hours formerly worked on the sixth day. There is no question that these cases indicate the marked superiority of the 5-day week over the 6-day week, with daily hours unchanged.

What, then, accounts for the apparently contradictory conclusions drawn from these cases and those examined in section A of this chapter, in which it was concluded that the sixth day, when added to a 5-day week, was nearly 100 percent effective in increasing output in direct proportion to the increased hours?

The answer very likely lies in the amounts earned. When hours were lengthened by the addition of the sixth day, all additional hours were paid for at time and a half. Under an incentive system, as most of the plants were, this meant one and one-half times the rates payable for work produced. Consequently there was a strong incentive to produce proportionately more on Saturday than on other days. The next day was Sunday, a day of rest. And, whereas daily hours were 10, the Saturday hours usually were 8.

On the other hand, when hours were cut back, this overtime was lost. Consequently there was the incentive to recoup as much of it as was reasonably possible during the shorter workweek—and therefore the higher efficiency and proportionately better output.

Obviously, then, the posing of the question whether, with daily hours kept constant between 8 and 10, there is any marked difference between the 5-day week and the 6-day week, involves determining first whether weekly hours are to go up or down. There is no question that, except perhaps for heavy work, a regular 6-day week results in greater output than is produced during the 5-day week. The case studies indicate that, as a rule, light operations could be carried on during the 6-day week at the same efficiency as during the 5-day week and that the additional output was almost in direct proportion to the additional hours worked. On the other hand, when hours were reduced after a sixth day had been worked for a protracted period of time, the 5-day week proved more efficient in terms of hourly output than was the 6-day week.

C.—5-day week vs. 6-day week; changes in daily hours

1. ADDING A SIXTH DAY.

In the 14 studies shown in table 7, comparisons are given for worker performances under 5- and 6-day weeks with changes (usually increases) in daily hours. In each instance, the comparison is for identical workers.

In the group of case studies for workers engaged in moderately heavy work, composed almost entirely of men, daily hours were usually raised from 8 to 9 or 10, and weekly hours from 40 to from 55 to 60. In spite of the fact that the work was machine-paced in study 7, both groups (a) and (b) performed more poorly at the longer hours. Efficiency was 5.0 and 6.0 percent

TABLE 7.—*Effects on efficiency and absenteeism by increasing weekly workdays from 5 to 6, with changes in daily hours*

[1] Where weekly hours are less than 6 times daily hours, shorter hours were worked on Saturday.

[2] Percentage of scheduled worktime lost.

[3] 3 days at 8 hours, 3 days at 10.

lower at the higher hourly level. In case study 67, the reverse was true. Here, however, operations were performed by semi-automatic machines and the longer workweek permitted a higher degree of utilization of the machines. Consequently, average hourly output, as reflected by the measure of efficiency, was 5.6 percent better.

In case study 65, the workweek was cut by 2 hours, and daily hours were 8 during the 6-day week as against 10 during the 5-day week. The shortening of the workday increased efficiency by 3.2 percent even though a sixth day had been added.

The sharp increases in daily hours from 8 to 10 and 11 in studies 20 and 21 resulted in drastic decreases in efficiencies—22.3 percent and 20.6 percent. Simultaneously, absenteeism rates doubled and tripled. The workers in both of these groups were engaged respectively on the day and night shifts of a plant producing shells. There certainly could not have been any closer connection with the war effort, and morale in the plant was good. Nevertheless, the large increases in hours curtailed hourly output sharply, and even the urgency of producing shells could not keep workers on the job steadily.

In the group of light, operator-paced operations, daily hours were higher during the 6-day week than they had been during the 5-day week. Generally, they had been raised from 8 to 9 or 10. Except for the two experiences shown for case study 50, parts (a) and (b), workers performed better at the higher levels of daily and weekly hours. Particularly marked are the efficiency increases in studies 25 and 26, in which 8- or 10-hour days were substituted for 7½-hour days. In case study 25, a group of 43 experienced male machine operators were engaged in high precision machining of small parts for guns and a variety of control devices for lubricating systems. In study 26, the group consisted of 25 experienced female workers engaged in assembling the small parts produced by men in study 25. In explaining the sharp increase in efficiencies of the two groups, plant management gave two reasons: (1) the participation of the employees in the war effort (during the longer schedule of hours) acted as a powerful stimulus to better worker performance; (2) the longer runs on each job during the longer workday spread unproductive time over a longer period of productive effort. Apparently the work during the longer workweek was not so hard as to cause a fatigue serious enough to bring about a slowing down of the workers. Conversely, the speed of the workers during the short workweek could not have been very fast, if it was possible for them to work so much faster during a very much longer workweek over a long stretch of time.

In study 38, efficiency was better at both 48 and 54 hours for a group of 8 women than it had been at 40 hours. The work performed was very light. It must be noted, however, that during the longer hours the percent of scheduled employee work-hours lost because of absenteeism rose to 11.8 and 14.4 percent, as against only 3.0 percent during the 40-hour week.

Case study 50 records the only serious drop in efficiency, 9.2 and 10.3 percent, respectively, when daily hours were increased from 8 to 9 or 9½, and weekly hours were increased from 40 hours to 53 and 48. The 24 female operators were engaged in packing candles in a candle-manufacturing plant and worked under a bonus system with three-quarter pay for all units produced in excess of set standards. In 50 (b), daily hours had been raised from 8 to 9, with an additional 3 hours on Saturday. In 50 (a) daily hours had been lengthened to 9½ with 5½ hours on Saturday. Although the efficiency level at this schedule was still decidedly poorer than that for 40 hours, it was somewhat better than it had been for the 48-hour week. The data indicate that the 3-hour Saturday was much too short to compensate for the additional hours worked. Furthermore, absenteeism losses were twice as high during the longer workweeks as they had been at 40 hours.

Table 8 shows the comparison of increases in weekly hours and increases in output.

In the moderately heavy types of work, the results are decidedly mixed. In studies 20 and 21, only 0.1 of an hour's output, measured at the 40-hour performance level, was gained for every additional hour worked, or, to put it more clearly, 1 hour's output for every 10 hours worked in excess of 40. What was accomplished in 60 and 66 hours could have been accomplished in 42 and 44 hours, respectively. The other 18 and 22 hours were completely wasted.

In case study 65, the decrease of weekly hours by 2, from 50 to 48, reduced output by only 0.4 of an output hour, obviously because of the better efficiency during the 8-hour day.

The semi-automatic type of operation in case study 67 explains the proportionately better output during the longer workweek. For every 5 hours worked above 40 per week, the equivalent of 6 hours' output was obtained.

TABLE 8.—*Effects on output by increasing workdays from 5 per week to 6, with changes in daily hours*

Case study and type of work	Weekly hours changed —		Percent change in —		Output-input ratio
	From	To	Hours	Output	
Machine-controlled pace:					
7a — Moderately heavy	40	58	+45.0	+36.0	0.8
7b — Moderately heavy	40	58	+45.0	+30.0	.7
Operator-controlled pace:					
20 — Moderately heavy	40	60	+50.0	+5.5	.1
21 — Moderately heavy	40	66	+65.0	+9.0	.1
64 — Moderately heavy	40	55	+37.5	+29.6	.8
65 — Moderately heavy	50	48	—3.9	—.7	.2
67 — Moderately heavy	40	55	+37.5	+43.6	1.2
74 — Moderately heavy	40	57	+42.5	+67.2	1.6
25 — Light	37 ½	58	+54.7	+81.2	1.5
26 — Light	37 ½	54	+44.0	+67.6	1.5
38a — Light	40	48	+20.0	+11.7	.6
38b — Light	40	54	+35.0	+22.6	.6
50a — Light	40	53	+32.5	+13.9	.4
50b — Light	40	48	+20.0	+ 3.3	.2

The explanation for the 1.6 output-input ratio for study 74, indicating 1.6 output hours gained for every hour worked above 40, is that the original pace under the 40-hour week had not been fast and that it was improved materially under the urgency of wartime needs. The 17 additional hours worked yielded the equivalent of 27 hours of output at the pace maintained during the 40-hour week.

In the group of light, operator-paced work, differences were less marked. Because of the sharp increases in efficiency, the output of the workers in studies 25 and 26 increased half again as much, proportionately, as did hours. But in each of the two other studies (38 and 50), output failed to keep up with increased hours. In study 38, nearly half the hours worked above 40 were nonproductive if the output level at 40 hours is used as a base of measurement. That observation is even more pertinent to case study 50, where 48 hours yielded only 41.3 hours of output (50 (b)), and where 53 hours of work yielded only 45.6 hours of output (59 (a)).

In comparison with the studies discussed in section A of this chapter, the performance of the workers discussed in section C is decidedly poorer. The obvious difference between the two groups is that the one discussed in this section experienced sharp increases in daily hours.

2. DROPPING THE SIXTH DAY.

In five studies, it was possible to observe the results of dropping the sixth day concurrently with changing daily hours. It two cases, 36 and 30, hours were lengthened during the 5-day week so as to offset the hours lost by dropping the sixth day, and still giving the workers a 2-day week end. In study 44, the company tried to accommodate itself to the needs of female workers under a 6-day week by using a schedule which gave them 3 days at about 6 hours, 1 at 5½ hours, and 2 at 8½. When the 2-day week end was introduced, hours were changed to a uniform schedule of 8.7 per day for each of the 5 days.

Case studies 72 and 78 present reductions in both daily and weekly hours. Operations in case study 78 were semi-automatic.

The 17 men in study 36 worked an 11-hour day and an 8-hour Saturday on the day shift, but shifted every 2 weeks to a 5-day, 12-hour schedule as a night shift. As table 9 shows, their efficiency was 6.1 percent better during the 5-day week, even though hours were 12 per day rather than 11.

The better performance of 10 female workers (case 30) during a 10-hour day, as compared with one of 7.7 hours, was due to a managerial change discussed earlier, which kept the operators at their machines constantly rather than requiring them to get and deliver their work materials. While the study shows that management can obtain better production by better work procedures, in spite of the lengthening of hours, it is not really a comparable measure of the effects of hours.

The regular workday of 8.7 hours proved more efficient than the irregular daily hours during the 6-day week in study 44. Efficiency was 2.1 percent better—but absenteeism during the longer workday schedule, although it provided for a free Saturday, rose from 2.2 percent for the irregular 6-day week to 9.7 percent under the longer workday.

TABLE 9.—*Effects on efficiency and absenteeism by decreasing weekly workdays from 6 to 5, with changes in daily hours*

[1] Where 6 times daily hours is less than total hours shown per week, shorter hours were worked on Saturday.

[2] Percentage of scheduled worktime lost.

[3] 3 days at 5⅚ hours, 2 days at 8½ hours, 1 day at 5½ hours.

[4] Not determined.

The net effect of these changes is shown in table 10. Here again all computations were made from the lower level of hours, as though hours had been increased from this level rather than reduced to it, so as to make the results comparable with earlier tables.

In study 36, the 3 extra hours worked on the day shift were more than wasted—the longer schedule actually produced less than the shorter one. Not only were the 3 additional hours nonproductive—the total output fell short of the output produced at 60 hours by the equivalent of 2.4 hours' production. At the performance level of the 60-hour week, the day shift could have reached its actual output in 57½ hours rather than 63.

Similarly, the 40-hour week in study 44 was nearly as productive as the 43½ hour week had been. The 3½ extra hours netted only 1 hour's output. A 41-hour week, with a workday of scarcely more than 8 hours, would have netted the same result.

As pointed out earlier, the semi-automatic operation in case study 78 made the work schedule for workers relatively unimportant. Output increased in direct proportion to hours of operation.

Case study 30 presents a different result. Here, in light and operator-paced work, the additional 4 hours worked produced 6.8 hours of additional output. But, as already explained, this study really does not measure the effects of a change in hours.

While the studies shown here are instructive, there are too few of them to permit any conclusions to be drawn.

TABLE 10.—*Effects on output by decreasing workdays from 6 to 5, with changes in daily hours*

Case study and type of work	Weekly hours changed —		Percent change in —		Output-input ratio
	From	To	Weekly hours	Output

30 — Light	46	50	+8.7	+14.9	1.7
44 — Light	40	43.5	+8.8	+2.6	.3
Machine-controlled pace:					
78 — Light	35	48	+37.1	+40.1	1.1

D.—6-day week vs. 5½-day week; no change in weekly hours

The frequency of high absenteeism rates for women during a full 6-day week has been mentioned briefly in preceding discussions. In some instances hourly schedules were altered deliberately so as to allow women time off for shopping and for attending to other personal matters that could be done only while stores and offices were open.

One such attempt was to provide for a half holiday on Saturday. So as not to lose any worktime, however, daily hours were increased sufficiently on the 5 full workdays to equal the total weekly hours during the full 6-day week.

The results of such a change were observed in six case studies, and are shown in table 11. While the number of workers observed in each instance was small, varying from 5 to 15, the results of these changes in work schedules were traced through periods of many months. Except for four men included in case study 39, all of the workers were women, and in each instance the speed of the operations was entirely under the control of the workers. All of them worked under group wage incentives in a plant manufacturing office supplies, and most of them were experienced workers who had been with the company for many years.

Except in one instance, study 41, daily hours on 5 days were increased from 8 to 8.8, and hours on Saturday were decreased from 8 to 4. In study 41, the hours on Saturday were 5½, and hours on the other 5 workdays were 8½.

In every instance the new arrangement of hours resulted in a higher efficiency. The increases ranged from as little as 0.3 percent to as high as 9.4 percent.

TABLE 11.—*Effects on efficiency, absenteeism, and output when changing from a 6-day week to a 5½-day week without changing weekly hours*

42 — Light	15	....do	48	8	8.8	4	+2.7	8.0	4.7	+ 6.3

[1] Percentage of scheduled worktime lost.

It may be of some significance that the highest efficiency increase took place in the group of four men and four women engaged in packing bundles for shipment, with the weight of materials handled varying from light to fairly heavy. The heavier work was done by the men. The effect of the new work schedule apparently was more marked where the physical exertion was greater.

The evidence as to the effects on absenteeism is not as uniformly in one direction. In study 39, the new arrangement had no effect on the absenteeism rate, which remained nearly the same. In studies 37 and 38, the absenteeism losses increased respectively from 0.5 to 4.4 percent of scheduled hours, and from 6.8 percent to 11.8 percent. On the other hand, the high rate of 22.1 dropped to 12.5 in study 40, from 18.5 to 5.5 in study 41, and from 8.0 percent to 4.7 percent in study 42. The higher absenteeism in studies 37 and 38 appears to have been due to a greater tendency to take off the half day on Saturday. On the other hand, the data suggest that the improvements in studies 40 and 41 may have been due largely to the fact that these workers frequently took off the one-half day on Saturday rather than a full day, as they had under the full 6-day week.

The increased absenteeism in studies 37 and 38 caused slight drops in total output, 1.0 and 2.8 percent, in these two groups. The other four groups, however, showed substantial improvements in the total output level, varying from a low of 6.3 percent to a high of 17.4 percent.

Generally, the 5½-day schedule appears to have been more effective than the full 6-day week for female operators.

CHAPTER IV.—6-Day Week

A.—Increases in daily and weekly hours

The most frequently observed method of lengthening weekly hours was to increase daily hours during a workweek of 6 days. The longer workday most frequently was of 9, 9½, or 10 hours' duration.

Except as other factors entered into the situation, hourly efficiency was poorer during the longer workday.

Case studies 22 and 23, involving men employed at hot and fairly heavy work in a foundry, show that hourly efficiency rose by 0.2 percent and 4.1 percent under the longer hours. These men worked at straight day-work rates and without wage incentives. As was found in similar instances elsewhere, the pace at the shorter hours under these conditions was not so fast at operations paced entirely by the operators but that it could be maintained during a longer schedule of hours—short, of course, of hours so long that fatigue would inevitably accumulate.

TABLE 12.—*Effects on efficiency and absenteeism of increasing daily and weekly hours, during a 6-day week*

[1] Where 6 times daily hours is less than hours shown, shorter hours were worked on Saturday.

[2] Percentage of scheduled worktime lost.

A 12.7-percent improvement in efficiency was found for the 14 men at moderately heavy work in a rubber plant. These workers, under an individual wage-incentive system, and under the urgency for much-needed rubber supplies during the war, found it possible to step up their average hourly output even though daily hours had been lengthened from 8 to 9½.

Case studies 30, 31, 32, 33, and 34 all reflect better hourly performances at light, operator-paced work during a 10-hour day than formerly at a 7⅔-hour day in a plant manufacturing air brakes. The workers were engaged in light operations at metal working machines, or in assembling and testing completed parts. Working conditions in the plant were exceptionally good, and the entire plant was air-conditioned.

The improvement in performance, while a real one, was not directly related to the change in hours, but to a managerial change which permitted the operators to spend all their time at their machines rather than spend part of it in getting new work materials and removing the loads of completed work. While these studies indicate the possibility of better worker performance under longer hours because of improvements instituted by management, the composition of the jobs themselves was so modified as to make the data noncomparable for the two work schedules. The studies are shown here to indicate that longer hours do not necessarily restrict production if other improvements can be made.

In the groups of heavy and moderately heavy work, studies 5 and 9 require comment. In study 5, 48 men were engaged in hot and heavy drop-forge work. When hours were lengthened from 9 to 10 per day, with 7 and 8 on Saturday, hourly efficiency dropped by 3.0 percent, although absenteeism remained fairly stable.

In study 9, 275 men were engaged in welding operations in the construction of various parts which were to go into battleships. The work involved considerable climbing about and permitted the use of individual initiative and resourcefulness. The work was not routinized, repetitive, or monotonous. Under these conditions, workers found it possible to maintain the same hourly efficiency under the 10-hour day and 58-hour week as they had under the 7½-hour day and 45-hour week. Their absenteeism, however, increased from a loss of 4.2 percent of hours scheduled to be worked to 6.9 percent.

In the group of light operations, all operator-paced, and generally consisting of repetitive, monotonous types of work, the general result of increasing daily hours—when no other factors were introduced to distort the comparison—appears to have been a drop in efficiency and an increase in absenteeism. Study 11, which indicates practically no change in efficiency, represents 66 female workers at day work without a wage incentive. The observation made earlier about the pace of day-rate workers under various levels of hours again applies here.

The ultimate criterion of the effectiveness of longer hours is the level of output. As table 13 shows, the longer daily work schedule, usually consisting of 10 hours or less, did result in appreciably more output than had been realized during the shorter schedules. Nevertheless, the increase in weekly hours rarely was matched by a proportionate increase in output. The only instances in which this did occur involved instances of managerial improvements (cases 30 to 34) and lack of wage incentives (cases 11, 22, and 23). The one exception in case study 74, in which the output gained paid off for the additional hours in a ratio of nearly two to one. This study was commented upon earlier.

Generally, however, the ratio of the equivalent of output hours gained to additional hours worked was about 0.6 or 0.7, indicating that 3 hours of work were required to produce the output of 2 hours at the shorter schedules. In terms of labor cost, at overtime rates, this means about 4½ hours' pay for 2 hours of additional output.

B.—Decreases in daily and weekly hours

In five studies the available data permitted conclusions as to the effectiveness of reducing daily and weekly hours while maintaining a 6-day week. This is the reverse of the schedule change discussed in section A.

As is apparent from table 14, all of the operations involved were heavy or moderately heavy and the speed of work was within the control of the operator.

The 48 men in case study 5 working at hot and heavy upset forging had their daily hours reduced from 10 to 9, with a consequent reduction in weekly hours from 58 to 52. This cut-back occurred a few months prior to the conclusion of the survey in this plant, and the ultimate leveling-off point of the rising efficiency under the shorter hours could not be determined. At this point, however, efficiency was better than at any point during the 58-hour week. Although absenteeism increased slightly under the shorter hours, from 2.8 percent to 4.2 percent, the output level at 52 hours was as good as that at 58 hours. In other words, as a long-run proposition, and disregarding the periods of transitional adjustment of the workers to the different schedules, workers at heavy work produced as much in 52 hours as they formerly did in 58. It would have been interesting to determine if an even lower schedule would have done as well. However, no lower hours were worked.

In study 18, 140 operators—of whom about 20 were husky women, selected for size and strength, and all others were men—were engaged in the

Table 14.—*Effects on efficiency, absenteeism, and output of reducing daily and weekly hours, during a 6-day week*

[Pace controlled by operator]

[1] Percentage of scheduled worktime lost.

[2] This is the last value observed for a sharply rising trend in efficiency after hours had been cut back to 52.

[3] Not determined.

production of metal landing mats under a group wage-incentive system. Daily hours were reduced from 10 to 8, and weekly hours from 58 to 48. Efficiency increased by 15.1 percent. The absenteeism loss remained about the same under both schedules.

A reduction of only 5 hours, by reducing daily hours from 9 to 8, brought about an 8.8-percent improvement in efficiency in case study 51. Here, 32 men were engaged in general foundry work. In case study 65, 14 men were engaged in heavy machining operations and in welding. A reduction in daily hours from 10 to 8 was followed by an increase of 6.3 percent in efficiency.

The improvement was least marked in case study 74, in which the improvement in efficiency was only 1.3 percent when daily hours were reduced from 9½ to 8. (But see comment on case study 74 on p. 154.)

As already indicated, output was as good at 52 hours as at 58 in the heavy work described in case study 5. Except for study 74, in which final output could not be computed, the output lost because of the shortening of hours was the equivalent of half or less of the hours reduced. In case study 18, using the output level at the shorter hours as a yardstick, only 4 hours of output had been gained because of the 10 extra hours worked. A 52-hour week would have been as good as the one of 58.

Approximately the same ratio held for the 14 men in case study 65. About 3.5 hours of output were gained for the additional 7 hours worked.

The ratio of output gained was still lower in case study 51. The equivalent output hours gained by working 9 hours a day rather than 8, or 48 a week rather than 53, amounted to only 1.5. In other words, it took 5 hours of work to produce 1½ hours of output. In terms of actual occurrence, only 1½ hours of output were lost when 5 hours were taken off the work schedule.

The studies indicate that for heavy or moderately heavy work during a 6-day week, the 8-hour day is superior to the 9- and 10-hour day and that, on the whole, for every 2 hours added to the workweek, only 1 hour's output—or less—was realized.

CHAPTER V.—7-Day Week

The 7-day workweek is generally recognized as undesirable. In the course of this survey, only four clean-cut cases of regular Sunday work could be studied. There were other instances of occasional Sunday work to break bottlenecks in production, but in none of these was the 7-day workweek used as a regular schedule.

In studies 27 and 28, made in a plant engaged in processing metal parts on a variety of metal working machines, the performances of 29 experienced male operators and 22 experienced female operators could be studied. The men worked on materials varying in weight from 1 pound to over 100 pounds and operated lathes, milling, grinding, and similar types of metal working machines. The women worked on smaller machines and handled materials varying in weight from 1 ounce to several pounds.

For the men, the comparison is between a workday of 8 hours for a nominal weekly total of 48 hours and a schedule which involved work on two additional Sundays a month. Actually, however, the nominal 48-hour week without Sunday work involved considerable overtime, so that daily hours frequently came to 10, and sometimes to as high as 15. The change from this schedule to the one requiring work on two Sundays a month therefore meant substituting the Sunday work for the irregular overtime. A complication, the effect of which could not be evaluated, was that the irregular overtime schedule preceded our entry into the war, whereas the Sunday work schedule occurred during the war.

In any event, the shift in the schedule meant a substitution of an average (over a month) of a 53.9-hour schedule per week for one of 51.5 hours. This slight change in weekly hours—but with alternate Sunday work substituted for irregular overtime—resulted in an increase of efficiency of 16.3 percent.

Scheduled worktime lost because of absenteeism, however, rose from 3 percent to 7.2 percent.

Although the higher absenteeism offset in part the improvement in efficiency, total output was 16.6 percent better. In part, this increase was due to a slightly higher average number of hours—53.9 hours as against 51.5, or an increase of about 5 percent. The 2½ additional hours netted the equivalent of 8½ hours of additional output.

For the 22 women operators (case study 28) the 2 days a month of Sunday work and the nominal 8-hour day on 6 days averaged to 52.5 hours per week per month. Later, but still during the war period, this schedule was replaced by a nominal 8-hour day for 6 days a week. Both schedules included a paid one-half hour lunch period, so that daily hours actually worked came to only 7½.

When Sunday work was eliminated, efficiency jumped by 22.9 percent. The reduction in the nominal work schedule, it will be observed, was from 52½ to 48 hours, a curtailment of only 9 percent. At the same time, the absenteeism loss decreased from 10.9 to 7.4 percent.

Total output was 16.7 percent higher under the shorter schedule, with Sunday work eliminated. The reduction in the average workweek of about 4½ hours netted 9 hours additional output.

The third study was one of the most interesting and revealing in the entire survey. It covered 30 identical operators in a small plant employing about 100 persons engaged in the production of drills and reamers.

The work was light and almost entirely operator-paced. Each worker was paid in full for all production in excess of fixed standards, with fixed increases for specified percentages of output above the standard. However, a ceiling on earnings limited pay for additional output to 30 percent, beyond which workers received no pay. The data revealed that workers did not exceed the production necessary to yield this result, although they could have done so.

In June 1944, when the survey was made, the plant was on three shifts of 8 hours each, for 6 days per week. This schedule was attained after several years of experience with Sunday work. The original schedule was 5 days at 8 hours, or 40 hours per week. Then followed a 48-hour week, with a sixth day added. This was followed by a 7-day week of 56 hours, continued for 5 months. The plant's absenteeism record had grown so bad by that time that it was shut down, first, every third Sunday, then every other Sunday, and finally every Sunday.

This study, therefore, pertains primarily to the effectiveness of Sunday work. The findings were as follows:

1. Efficiency was highest during the 6-day, 48-hour week. In comparison with the average output per hour worked during the 7-day, 56-hour week, the average efficiency level during the shorter workweek was 29 percent greater.

There is reason to believe that the level during the shorter workweek would have been higher still had it not been for the company's bonus policy, under which production in excess of 30 percent above the standard was not compensated. This fact probably explains why there is only a 1-percent difference between the average hourly efficiency during the 6-day week and the schedule under which employees worked every other Sunday.

When employees were given every third Sunday off, after a long stretch at 7 days per week, efficiency jumped by nearly 17 percent. It went up another 11 percent when the plant worked only every other Sunday. If a similar improvement is assumed in the absence of a bonus scheme which sets a maximum limit on production, the estimated hourly output during the 6-day week would be still higher, by 6 to 8 percent. In other words, the data suggest that, had there not been the bonus limitation, the average efficiency during the 6-day, 48-hour week would have been one-third again as high as that of the 7-day, 56-hour week.

Not only was the 7-day week more costly: it was also only about 75 percent as efficient as the 6-day week.

As the chart shows, efficiency clearly improved as additional Sunday work was dropped. Efficiency was lowest when all Sundays were worked, and highest when no Sundays were worked.

2. The time lost because of absenteeism by the 30 selected operators was lower when Sunday work was discontinued entirely, as against the schedule under which every other Sunday was worked. The relative percentages, 7.3 and 8.2, appear to be quite high. The average time losses during the two earlier periods—4.1 percent when every Sunday was worked and 7.8 percent when 2 Sundays were worked out of 3—are not directly comparable with these figures because during the earlier schedules the company paid an attendance bonus: $5 for perfect attendance during the first month, $10 for the second month, and $15 for the third.

When Sunday work was scheduled, absenteeism was highest on Sunday. Next in order came Saturday; and third, Monday. Attendance was best on Friday—but Friday was pay day.

Management attempted to curb absenteeism by listing the names of the absentees. But the operators apparently did not care. In explanation of the high absenteeism rates, management advanced two reasons: (1) The 7-day week was too long. The men were tired and wanted some time off, even though it meant the loss of the attendance bonus and double pay for Sunday work. (2) Earnings were high, and the men had no time to spend their money. (The weekly bonus varied between $5 and $25, averaging about $10 per employee. Good operators averaged earnings of $1.50 to $1.65 an hour.) Consequently the value of money shrank, and the social aspects of spending some time with their families and friends assumed larger proportions with the operators.

3. Under the limitations of bonus earnings, the output of the 30 selected—and skilled—operators was highest during the schedule calling for work on every other Sunday, i.e., 1 week at 7 days and the next at 6. If the assumption of the efficiency level in the absence of the bonus limitation is sound, however, it appears that the output level during the straight 6-day week, at 48 hours, would have been equally as high.

Sunday work clearly was not economical. Instead of increasing weekly output, it actually decreased it—and at higher labor cost.

In case study 24, the performances of 31 men were traced through two long periods, the first of which required 8 hours of work for 7 days a week for a 54-hour week, and the second called for a 10½-hour day, with 8 hours on Saturday, for a total of 58 hours, but with no Sunday work. (The 8-hour day included a 15-minute lunch period, and the second, a one-half hour lunch period, both of which were paid for by the company. The lunch period has been excluded in the computation of actual results.)

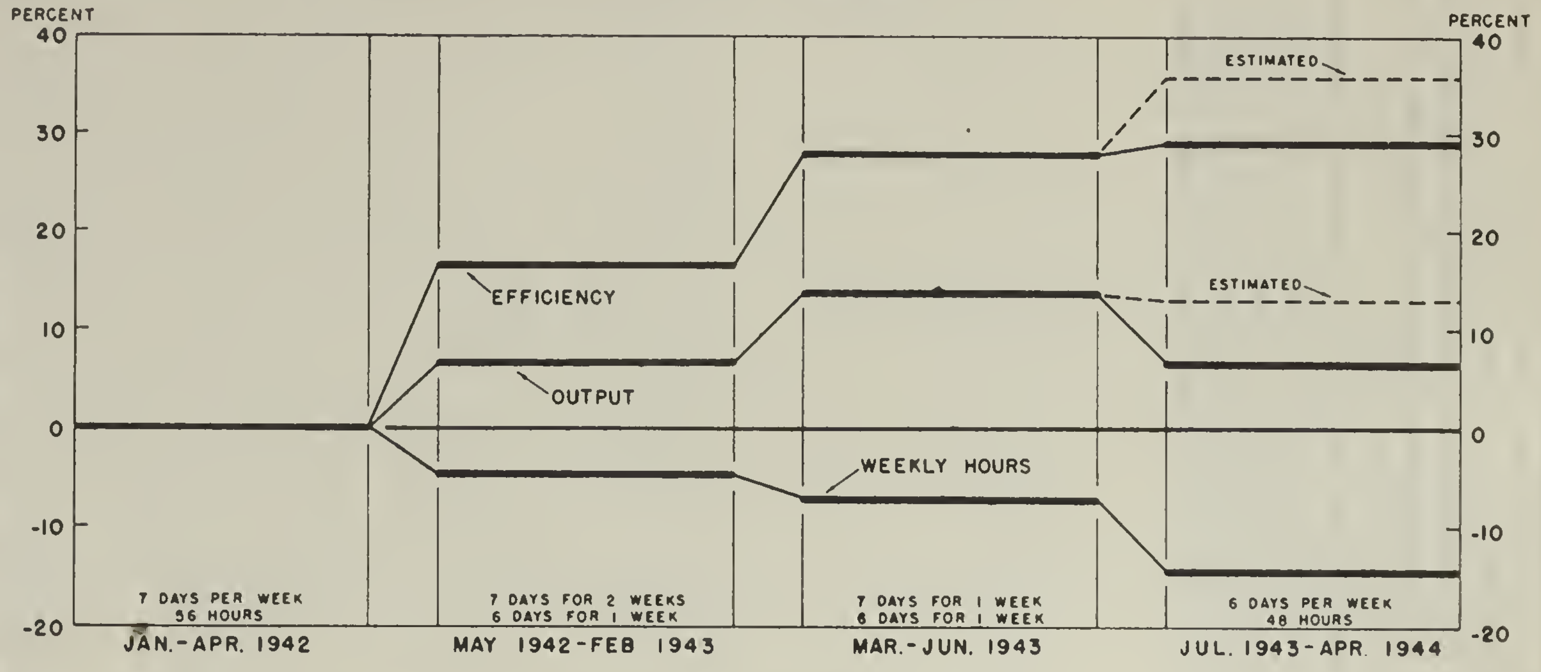
The men machined small metal parts for machine-gun tripods, aircraft engines, and other military equipment. The work was light and operator-paced.

Although there was no direct wage-incentive system, workers were paid specified hourly rates only if they maintained specified levels of output. Upgrading of rates was predicated on efficiency of performance.

CHART I

CHANGES IN AVERAGE WEEKLY HOURS, EFFICIENCY, AND OUTPUT

30 MALE OPERATORS



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Efficiency was better by 14.3 percent without Sunday work, even though daily hours had been lengthened from 7¾ to 10. Absenteeism was about the same under both schedules and amounted to a time loss of 5 percent of scheduled man-hours. The absence peak during the 6-day week fell on Saturday, reflecting the desire or need for a longer week end. Under the Sunday schedule, attendance was worst on Sunday, with Monday only slightly better. Operators who worked on Sunday, at double pay, frequently took Monday off, losing only straight pay.

The longer workweek was more productive than the Sunday work schedule. Although weekly hours had been increased by only about 7 percent, output increased by somewhat better than 22 percent. The elimination of Sunday work not only saved the cost of double pay for that day, but also netted 15 percent of output beyond the 7 percent of additional hours worked.

CHAPTER VI.—Intermittent Work Schedules

In some industries, of which clothing manufacturing perhaps is a good example, irregular hours were worked frequently during the war. In part, this was the result of shortages of materials at various times, and, in part, the pressure to get orders finished on schedule when materials were available. Case studies 52 to 57 trace the performances of workers at various types of operations in plants manufacturing clothing. Hours varied from 24 per week or less to as high as 55. As the work pace was fast, the results obtained at the various schedules are fairly good indications of the effects they engender should they be worked as regular, sustained schedules.

A Rural Plant

Studies 52 and 53 were made at a plant manufacturing men's trousers. The plant was located in a small rural community, and many of the operators had outside interests such as farming, gardening, hunting, and fishing. During the planting and harvesting seasons, their tendency was to hold work hours to an absolute minimum so as to have the time for these other activities. Most of the workers had high school educations, were self-reliant, and skeptical of anything that smacked of company patronage. In turn, management made no effort to make the plant or working conditions comfortable or attractive.

For the 96 women discussed in case study 52, work schedules varied from 24 hours to 48. All operations were performed at power sewing machines and were entirely paced by each operator working at piece rates. Hourly earnings averaged about 80 cents and ranged from as low as 60 cents to as high as $1.25.

The highest efficiency level, i. e., output per hour worked, was obtained for a workweek of 24 to 28 hours. At successive levels of 32, 36, and 40 hours, efficiency was slightly lower, but did not vary appreciably. But the 48-hour week was 4 percent poorer in efficiency than the 40-hour week, and 7.1 percent poorer than the 24-hour week.

Because of the nature of available records, and the intermittent schedules, it was not possible to determine absences that lasted an entire week or more. The figures used reflect absences of less than a week. Measured on this basis, the absenteeism loss increased slowly but steadily as hours increased from 24 to 40, when it reached 6.3 percent of scheduled hours. But at 44 hours it was only 3.3 percent, and at 48 hours, 1.2 percent. Obviously the workers were anxious to earn the time-and-a-half pay for overtime.

As a general rule, weekly output increased in direct proportion to hours. As hours exceeded 40, the lower efficiency was offset by better worker attendance.

In the same plant, 13 male pressers were studied for work schedules varying from 20 to 55 hours (study 53). Here, too, the pace was fast. The physical demands on the operators of the presses, however, were much more severe. Work frequently was hot and humid. Earnings averaged $1.10 per hour.

As in the case of the sewers, the efficiency of the male pressers was highest during the 24 to 28 hour week. Again, as in the case of the sewers, the efficiency level decreased slowly but steadily as hours rose to 40, for a total drop of about 3 percent. After 40 hours, efficiency dropped more sharply. The 55-hour week was 6 percent poorer than the 40-hour week, and 9 percent poorer than the 24-hour week. It is significant, however, that hours below 24 were not as efficient as those from 24 to 28.

Similar to the absenteeism experience of the women operators, the loss percentage for the men rose steadily to 7.8 percent at 40 hours. And again, as in the case of the sewers, work attendance at hours above 40 was very much better. At 44 hours, absenteeism caused a loss of only 1.9 percent of scheduled hours, and at 48 hours, attendance was perfect. At 55 hours, however, time lost had risen slightly to 1.2 percent.

Weekly output generally kept pace with changes in weekly hours, the lower absenteeism rates at the hours above 40 offsetting the lower efficiencies. The downward trend in efficiency, however, indicates that weekly output would have suffered rather severely had the long hours been sustained for any long period of time.

An Urban Plant

A direct comparison with studies 52 and 53 is provided by studies 54 and 55. Here, too, sewing and pressing operations were studied, but on the production of military and civilian overcoats. The plant belonged to the same company, but was situated in an industrial city. As in the rural plant, working conditions were only fair and entirely functional, without much regard for the comforts of the workers.

The experiences of 32 skilled female operators of power sewing machines furnish the material for study 54. Pace, wage incentive, and nature of work were the same as in case study 52. There was, however, this important difference—neither the women in this study, nor the men in study 55, were concerned with such outside activities as gardening and farming. Earnings averaged about 90 cents an hour.

During the 20-month period surveyed, weekly hours ranged from 28 to 52. The nominal workweek, consisting of 5 days at 8 hours each, was revised constantly, depending on the volume of work at hand and the work flow.

Contrary to the experience of the rural group, efficiency increased as hours were raised from 28 to 40. At that level, efficiency was 6.3 percent better. However, when hours exceeded 40, this trend was reversed. In spite of overtime pay, efficiency at 44 hours was 1 percent poorer, and at 52 hours, 3 percent poorer than at 40.

Contrary again to the experience of the rural operators, absenteeism remained fairly stable, at about 5 percent, for the schedules from 28 to 40 hours. But, as in the other case, attendance improved as hours exceeded 40 —at 44 hours it was 2.3 percent, and at 52 hours, 0.6 percent. Here, too, the better attendance may be attributed to the desire to take full advantage of the overtime pay and to make up for the loss occasioned by short work schedules. It is likely, however, that the picture might have been considerably different had the longer schedules been worked regularly rather than intermittently. As it was, total output kept pace with the increased hours, with lower absenteeism offsetting lower efficiencies.

The 22 hand and machine pressers in case study 55 afford a direct comparison with the pressers in study 53. The work required skill, and working conditions were similar to those described in the earlier study. The nature of the work—pressing overcoats rather than trousers—made for a steady but somewhat slower pace.

Hours fluctuated between 28 and 52. As in the case of the sewers in this plant, and contrary to the experience of the pressers in the rural plant, efficiency increased as hours rose from 28 to 40. At that level it was 4.9 percent better than at 28 hours. But as hours exceeded 40, efficiency leveled off. However, it remained fairly constant at 40, 44, 48, and 52 hours. The obvious explanation for this is the slower pace.

Contrary to the experience of the three other groups discussed thus far, absenteeism varied little with changing schedules of hours. Again, however, it is questionable whether a sustained 48- or 52-hour week would have had the same result.

Output increased in almost direct proportion to increased hours, with both efficiency and absenteeism constant above 40 hours.

Quality Rather Than Quantity

A third comparison was provided by sewers and pressers in the urban plant, but engaged in the manufacture of military and civilian jackets. This work, however, was subjected to much stricter quality controls. In spite of the piece-rate system, the emphasis was on quality rather than quantity of work. As a consequence, the pace was steady and unhurried. Furthermore, working conditions were considerably more comfortable.

Study 56 provides the findings for the results of constantly changing work schedules for 123 female operators of power sewing machines and hand sewers. Hours varied between 28 and 52.

As the study indicates, hourly output improved slightly as hours moved up to 40 per week, at which efficiency was nearly 3 percent better than at 28 hours. Efficiencies at 44, 48, and 52 hours were about 1 percent better. Working at a slower pace, these workers could maintain a steady hourly output in spite of the longer hours. These hours, however, were worked intermittently rather than steadily.

The absenteeism rate reached its highest point, 6.8 percent, at 32 hours, and was 6.1 percent at 40 hours. As in the other studies, absenteeism dropped sharply after 40 hours, with 2.1 percent for the 44-hour week and 1.1 percent during the 52-hour week. But, again, these rates probably would have been considerably higher had the longer schedules been worked steadily.

Improved attendance at somewhat better efficiencies and the higher hours resulted in proportionately better output levels. Although the 44-hour week represented an increase of only 10 percent above the 40-hour level, output was 15 percent higher. When hours were increased by 30 percent to a level of 52, output was 39 percent higher.

The 29 male hand and machine pressers in case study 57 had much the same experience. Here, too, the emphasis was on quality, and the work pace consequently deliberate and steady, rather than fast.

Efficiency improved somewhat, 2.1 percent, as hours increased from 28 to 40. As in the case of the sewers, efficiency rose by about 1 percent above that at 40 hours when hours increased to 44, and remained at that level even though hours increased to 52.

Although the absenteeism rates were somewhat lower than for the female sewers, the trend was the same, with 3 percent at 40 hours. During the 44- to 52-hour weeks, absenteeism dropped to 1 percent or less.

Paralleling the output experience of the sewers, the output for the pressers was somewhat better during the 44- to 52-hour schedules than during the shorter workweeks. At 44 hours, output exceeded the proportional increase in hours by 3.1 percent, and at 52 hours, by 4.3 percent.

In conclusion, however, it must again be emphasized that the results observed apply to intermittent schedules. They show the drive of overtime pay during hours above 40—but for schedules worked irregularly and not sustained over a long period of time. Had these longer schedules been sustained, the results might well have been different.

CHAPTER VII.—Work Injuries

In general, the results of the survey indicate that work injuries increased disproportionately as hours increased.

In table 15 are shown the frequency rates of injuries—i. e., the average number of injuries per million employee-hours worked—at various levels of weekly hours. Most of the plants included in this table were not included in the basic survey on the effects of hours because the type of data needed for output computations was not available. The data covers the experiences of about 85,000 workers.

Where possible, frequency rates were computed for all work injuries—for those that were disabling as well as those that required only first aid.

A study of table 15 reveals some inconsistencies in the general upward trend of injuries. The reason for some of these can be explained because these studies were included in the more comprehensive survey. For example, plant S had a frequency rate of disabling injuries of 13.7 at 48 hours. At 54 hours, the rate was nearly the same, 13.1. The explanation is a very efficient system of accident prevention.

An entirely different reason explains the lower over-all frequency rate for plant T at 60 or more hours than had prevailed at 40 hours. These figures summarize the findings for case studies 20 and 21. Reference to these studies readily reveals that the operating pace had slowed down so much—by more than 20 percent—that injuries were somewhat fewer, in terms of the million-hour base. It is readily apparent, however, that the slight reduction, about 5 percent, stands in sharp contrast to the slowing down in the operating pace.

In five plants (D, H, L, M, and Q), the reasons for the better rates at higher levels of weekly hours could not be ascertained.

TABLE 15.—*Frequency rates of work injuries at various levels of weekly hours*

Plant	Frequency rates of injuries at weekly levels of —							
	40 hours		48 hours		54 hours		60 or more hours	
	Disabling	Total	Disabling	Total	Disabling	Total	Disabling	Total

M	46.4	....	....	....	41.5	....	....	....
N	60.0	....	62.4	....	....	....	....	....
O	26.5	....	....	....	....	....	30.2	....
P	8.1	....	....	....	19.2	....	....	....
Q	....	....	16.6	....	....	....	11.4	....
R	32.9	....	37.1	....	....	....	....	....
S	....	....	13.7	....	13.1	....	....	....
T	....	6.337	....	....	....	....	....	6.017

On the other hand, the evidence of the effect of longer hours on work injuries is rather striking. In plant A, with hours increased from 40 to 48, the frequency rate went up by more than 50 percent. Similar results were obtained in plant C, when hours went up from 48 to 54, and in plant B, when hours rose from 54 to 60. In plant G, an increase from 40 hours to 48 just about doubled the over-all frequency rate, and in plant J, an increase from 48 hours to about 60 nearly tripled the rate.

In plant N, the rate at 48 hours is only about 4 percent above that for 40 hours. It probably would have been higher had there not been a fairly sharp curtailment in average hourly output at 48 hours in this forge shop in which work was both hot and heavy.

In plant O, the increase in the frequency rate of disabling injuries reflects a rise of only about 14 percent. This considerably understates the situation because foremen "covered up" at the higher hours by not reporting the minor types of disabling injuries—i. e., those that disabled men for 1 or 2 days, but could be taken care of satisfactorily by the nurse.

An instance of the inability of an excellent safety program to cope with the disproportionate increase in injuries is supplied by plant P. Here the frequency rate for disabling injuries was 8.1 at 40 hours, but 19.2 at 54 hours.

Because of the difference in record keeping for minor injuries, the rates for the plants shown are comparable only for disabling injuries, but not for all work injuries. Basically, the findings reflect the effects of different work schedules and not plant differences.

The Hourly Injury Pattern

Regrettably, it was not possible in a single instance to match injuries by hour of occurrence with hourly output, particularly when hours per day were increased. In one plant, however, it was possible to develop the hourly pattern of injury occurrence for all injuries, most of them nondisabling. The distribution of these injuries during both an 8-hour day and a 10-hour day schedule are shown in table 16, and graphically on chart 2. The 8-hour day schedule covered a period of about 7 months, and that of the 10-hour schedule, about 9½ months. The group surveyed consisted of 100 workers. (See pp. 39 and 40.)

The hourly distribution of injuries under the two patterns of daily hours is very similar. In both cases, the first hour has the lowest number of injuries. During the 8-hour day, the curve rises slowly during the 2nd and 3rd hours, but reaches a peak with nearly 17 percent of all injuries during the fourth hour of a 5-hour stretch. During the fifth hour, the percentage drops to 12, reflecting the slowing down in pace as the lunch hour approached.

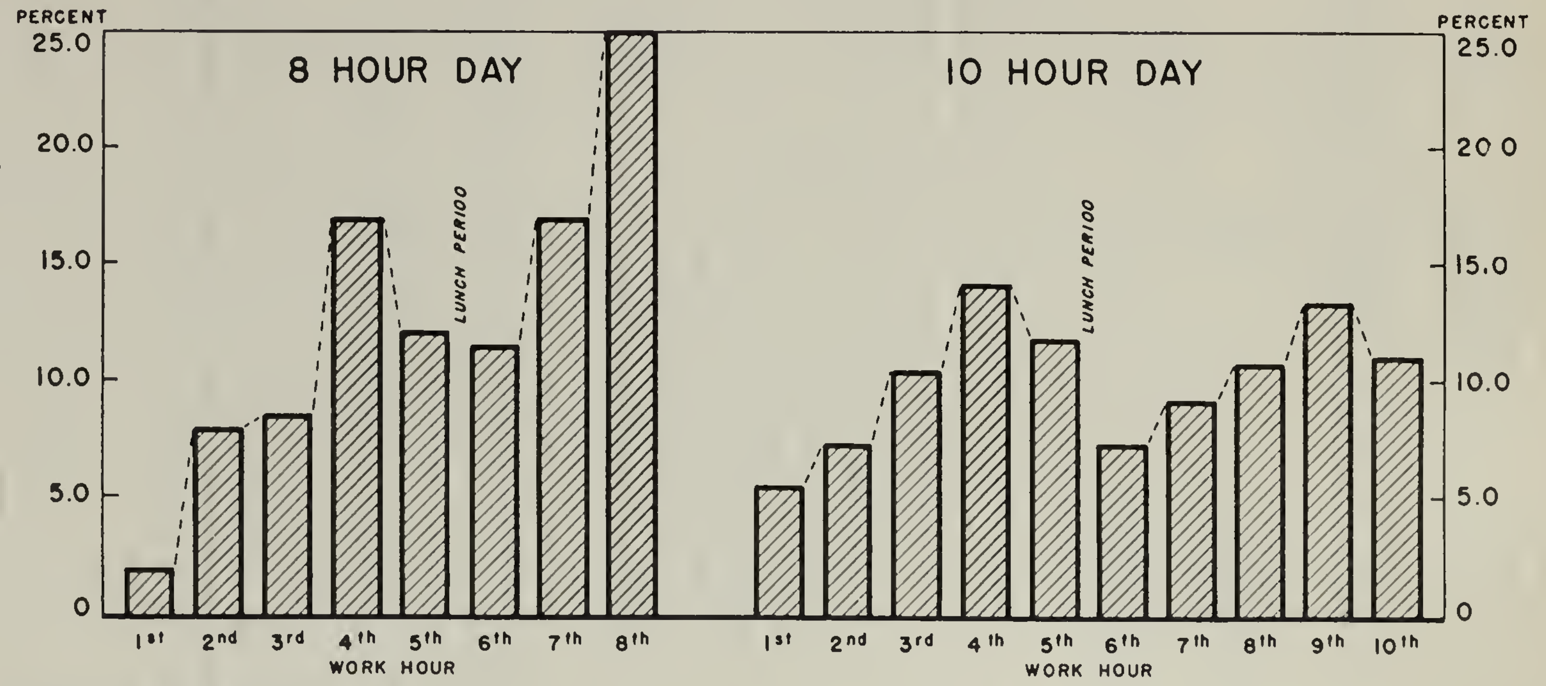
During the 3-hour stretch in the afternoon, however, injuries rise steadily and sharply. Beginning at 11.4 percent, the increase is to 16.8 percent, and finally, 25.0 percent in the last hour.

With hours unevenly divided for morning and afternoon work—5 and hours rather than 4 and 4—the 3 hours in the afternoon account for 53 per

CHART 2

DISTRIBUTION OF WORK INJURIES BY HOUR OF OCCURRENCE

DURING 8 AND 10 HOUR SCHEDULES



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

cent of all the injuries. The high percentage of injuries falling into the last hour may reflect fatigue or a burst of speed, or both.

TABLE 16.—*Distribution of work injuries by hour of injury occurrence, for an 8- and a 10-hour day*

Hour of injury occurrence	8-hour day		10-hour day	
	Number of injuries	Percent of total	Number of injuries	Percent of total
Total	167	100.0	429	100.0
First hour — 7 o'clock	3	1.8	23	5.4
Second hour — 8 o'clock	13	7.8	31	7.2
Third hour — 9 o'clock	14	8.4	44	10.3
Fourth hour — 10 o'clock	28	16.8	61	14.1
Fifth hour — 11 o'clock	20	12.0	50	11.7
Sixth hour — 1 o'clock	19	11.4	31	7.2
Seventh hour — 2 o'clock	28	16.8	39	9.1
Eighth hour — 3 o'clock	42	25.0	46	10.7
Ninth hour — 4 o'clock	....	....	57	13.3
Tenth hour — 5 o'clock	....	....	47	11.0

Like the 8-hour day, the 10-hour day also reaches its morning peak during the fourth hour and then drops off during the hour immediately preceding the break for lunch. During the 5-hour afternoon, the distribution of injuries has not nearly the intensity displayed by the 8-hour day. The first and second afternoon hours are comparable to the second and third morning hours. In fact, the fourth hour morning peak is not reached at all in the afternoon. Like the fourth hour in the morning, the fourth hour in the afternoon stretch is the high point for the half day. The 5-hour afternoon accounts for exactly 50 percent of the injuries. The sharp upward surge during the last hour of the 8-hour day is entirely missing. Instead, there is a dropping off during the last hour, which is not much worse than the third morning or third afternoon hour.

In the absence of hourly production data, any attempted explanation for these differences can be no more than informed guesses. The explanation that suggests itself most readily is that the operating pace during the 10-hour day, with the day divided evenly by the lunch hour, is a more steady pace than that for the 8-hour day. There, too, the injury distribution might have been different had the day been divided into two stretches of 4 hours each. But with only 3 hours in the afternoon, with a pause for lunch to refresh them, it seems that the operators worked up to another production peak during the afternoon, as they had during the fourth hour in the morning, but to a higher level. In other words, the poorer injury experience during the short afternoon stretch may have been the direct result of a fast production pace.

CHAPTER VIII.—Daily Patterns of Efficiency and Absenteeism; Various Levels of Hours

It was hoped that the data on efficiency and absenteeism might reflect aily output and absenteeism patterns that might be characteristic for the arious levels of daily and weekly hours.

Efficiency

Owing to the scattered instances in which it was found possible to obtain ata in sufficient detail, the patterns for efficiency are not numerous enough o permit any definite conclusions. Some of them, however, reveal a definite rend when performances at various schedules are examined for the same roup of workers.

In table 17 are shown daily efficiencies on 8-, 9-, and 10-hour days with orkdays varying from 5 to 7.

TABLE 17.—*Daily efficiency patterns at various schedules of daily and weekly hours*

Case study and type of work	Sex of workers	Work schedules	Daily efficiencies						
			Mon.	Tues.	Wed.	Thurs.	Fri.	Sat.	Sun.
		8-hour day							
7 — Mod. heavy....	Male	5 days at 8 hours	99.0	98.3	99.8	102.2	100.6	..	..
8 — Light..........	....do	....do	98.8	100.6	100.0	100.6	99.7	..	..

8 — Light..........	Male	6 days at 8 hours	99.2	100.1	100.9	99.8	99.8	100.1	..
9-63 — Light.......	Female	....do	99.9	101.0	99.4	101.2	98.7	99.5	..
4 — Light..........	Male	7 days at 7.7 hr.	98.3	98.2	97.6	97.6	102.3	101.1	104.6
8 — Light..........	Female	7 days at 8 hours	98.6	101.2	100.4	100.8	102.2	99.1	97.8
		9-hour day							
5 — Heavy.........	Male	5 days at 9 hours 1 day at 7 hours	94.8	105.9	109.6	96.1	94.8	98.5	..
		10-hour day							
7 — Mod. heavy....	....do	5 days at 10 hr.	99.4	101.0	99.4	100.2	100.2	..	..
5 — Heavy.........	....do	5 days at 10 hr. 1 day at 8 hours	98.0	99.3	102.0	102.0	100.7	98.0	..
4 — Light..........	....do	....do	99.8	99.6	100.1	99.8	99.5	101.1	..
7 — Mod. heavy....	....do	....do	99.8	98.9	99.8	100.6	100.6	100.6	..

During the 40-hour week, with an 8-hour schedule for 5 days, case study 7, ith men engaged at moderately heavy work, suggests a gradual building-up o a peak on Thursday. In study 78, with men at light work, the pattern is omewhat similar, except that a high plateau prevails on Tuesday, Wednesday, and Thursday, with somewhat lower efficiencies on Monday and Friday, he first and last days of the week. The grouped results for the women operaors in case studies 59 to 63, however, suggest a fairly constant daily pattern, xcept for a slight drop on Tuesday.

Adding a sixth day at 8 hours does not appear to have altered the pattern uch for the male operators in case study 78. However, it definitely depressed the level of the daily performances of the women operators in case studies 59-63.

The 7-day patterns shown for studies 24 and 28 do not follow a similar distribution. In case study 24, the men performed better on the last 3 days of the week, with particular emphasis on Sunday, when the best performance was turned in. This is rather surprising because the work was not done at piecework or under any other direct incentive system. Although double time was paid for Sunday, the pay would have been the same even if a lower output level had been reached. The reason for this pattern is anything but clear.

The pattern supplied by the women operators in case study 28 shows Sunday performance to be poorer than that of any other day, but not substantially so—only about 2 percent below the average for the week. Here, moreover, workers were paid in full for all time saved from the standards allowed for each job.

Only case study 5 supplies a pattern for the 9-hour day. The schedule actually consisted of 5 days at 9 hours, with Saturday at 7 hours. The pattern, for men at heavy work, shows a surprisingly sharp rise from a low of 94.8 on Monday to a high of 109.6 on Wednesday—but with sharp decreases on Thursday and Friday, with Friday back to the Monday level. Performance recovered to an index of 98.5 for the shorter Saturday. The reason for the sharp spurt on Tuesday and Wednesday is not apparent.

During the 10-hour day, the men in case study 7, at moderately heavy work, performed almost uniformly well on each of the 5 days of the workweek. In comparison with the 8-hour day, however, it is quite clear that the midweek spurt disappeared. The addition of a sixth day at 8 hours, lengthening weekly hours to 58, also reveals the absence of the midweek spurt, and indicates that the level for the entire week was somewhat lower than that for the 50-hour week. In other words, as daily hours were raised from 8 per day to 10, but with the retention of the 2-day week end, the midweek spurt was lost. When a sixth day was added, the curves remained flat, but dropped to a still lower level. (See chart 3.)

The men at heavy work in case study 5 reveal the same experience under the 9- and 10-hour day patterns. A reference to table 17 shows the sharp spurt on Tuesday and Wednesday substantially reduced. Here, too, the effect of lengthening daily hours was to curtail the spurt, and to level out daily production. It is to be noted, however, that performance on Thursday and Friday was substantially better during the longer work schedule.

The performance of the men in case study 24 also indicates that for a 10-hour schedule, the performance on any one day was about as good as on any other day. Here again, efficiency was better during the shorter Saturday.

Although available details are insufficient to justify any definite conclusions, the available data suggest that the 6-day week at 8 hours a day is nearly as good in terms of efficiency as the 5-day week at 8 hours. But when hours are raised to 9 and 10, the midweek peak tends to disappear, and the curve becomes flat. As a sixth day is added, the curve remains flat, but drops to a still lower level.

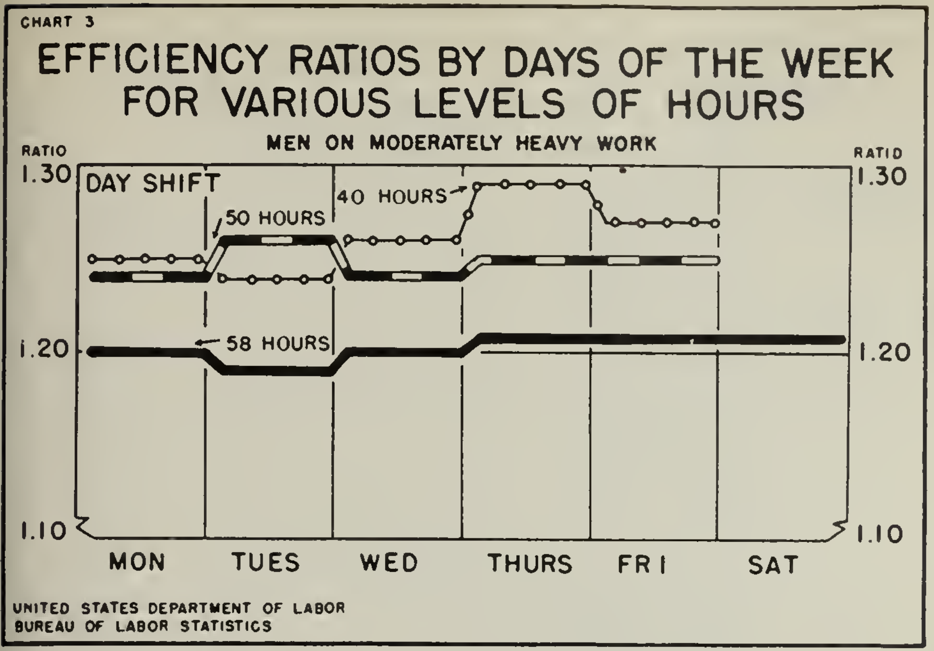

CHART 3

EFFICIENCY RATIOS BY DAYS OF THE WEEK FOR VARIOUS LEVELS OF HOURS

MEN ON MODERATELY HEAVY WORK

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

This trend suggests one other conclusion: As efficiency drops at longer laily and weekly schedules, the performance of each day of the week is oorer under the longer schedule. Lower hourly production does not manifest tself merely during the additional hours worked—it pervades the entire work chedule. At longer hours, workers tend to slow down so as to be able to tretch their energies over the longer schedules.

Absenteeism

Attention has been called earlier to two important aspects of absenteeism: 1) the generally higher absence rates for women and (2) the general increase in scheduled worktime lost when hours were raised substantially above 8 per week.

Table 18 shows how the absenteeism pattern varies, by days of the week, nder various schedules of daily and weekly hours.

Although the levels of absenteeism rates vary considerably between plants, o definite daily pattern is discernible for any one plant during the 5-day veek with the 8-hour day, except, perhaps, a somewhat higher rate on Monlay, the first day of the week.

When the workweek was lengthened to 6 days by the addition of another -hour day, the pattern displays a markedly higher rate for Saturday.

In case study 69, the Saturday rate is twice that for any other day in he week, although the rate of 3.8 is low in comparison with the rates of most f the other worker groups shown. Case study 70 indicates not only the endency to take Saturday off, but also to take Monday off. One obvious xplanation for this is that the men who worked on Saturday found it necesary or desirable to take time out on Monday. There is little time for shoping or for attending to personal matters or needs when the workweek enompasses 6 full days.

TABLE 18.—*Daily absenteeism patterns at various levels of daily and weekly hours*

Case study	Sex of workers	Schedule	Percent of scheduled worktime lost through absences

The situation was reversed for the night-shift crew of men in case study 71. There, work began on Sunday night—and, as one might expect, absenteeism was highest on this first night of the week rather than on the last. In fact, it averaged 13.7 percent of the hours scheduled for work on that shift. Here the explanation is based on social grounds. After spending the day with his family and friends, the worker is not apt to feel fresh enough to report for work at night. The alternative is to sleep away a considerable portion of the day—but that means foregoing the social intercourse which is such an important part of life.

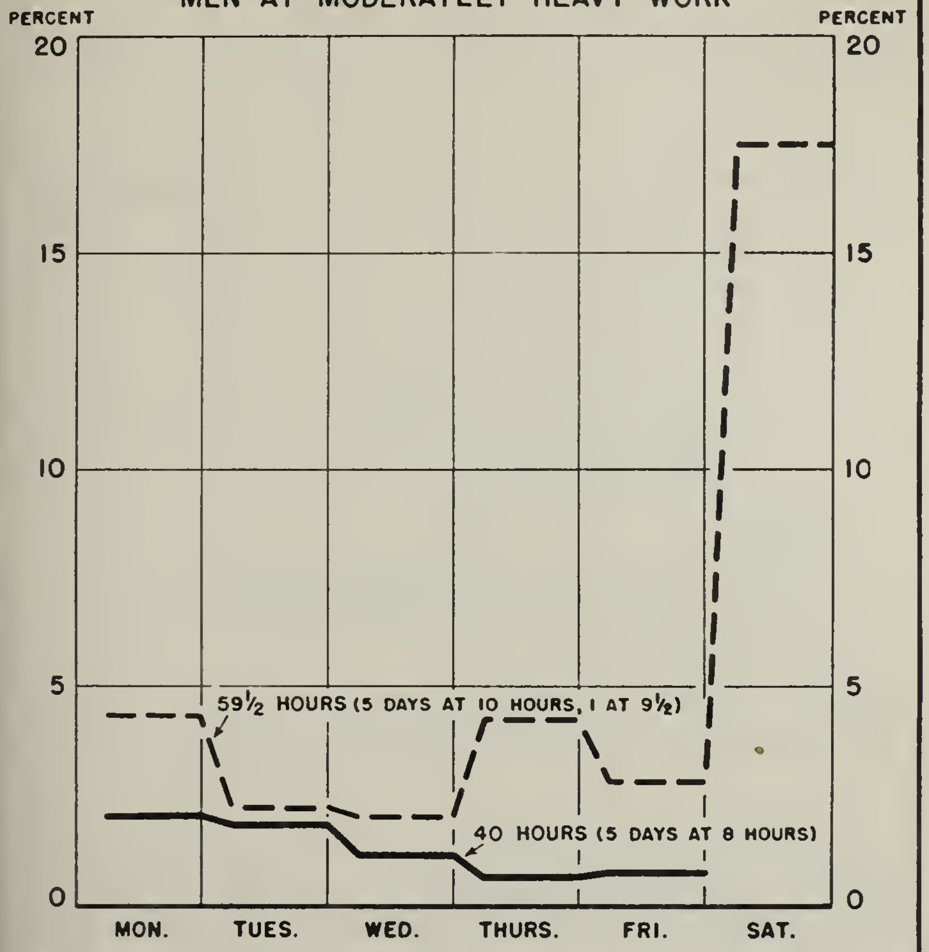
The absenteeism rates for the combined group of female operators in case studies 59 to 63 illustrate the generally higher absenteeism pattern for women. The same is true of case study 28. On the other hand, this pattern is not true of all women, as shown by the operators in case study 77. But here, as in studies 59 to 63, the significance of Saturday work is unmistakable: absenteeism rose to above 20 percent. In other words, on an average, fully one-fifth of the total work force consisting of women stayed away from work. This, it will be observed, represents an absenteeism loss about three times as high as that observed for men.

The explanation suggested for the men applies with even greater force to the women. To it must be added the fact that many women workers have home responsibilities and, often, the responsibility of taking care of children.

CHART 4

DAILY PATTERN OF ABSENTEEISM DURING 5 AND 6 DAY WEEKS

MEN AT MODERATELY HEAVY WORK



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

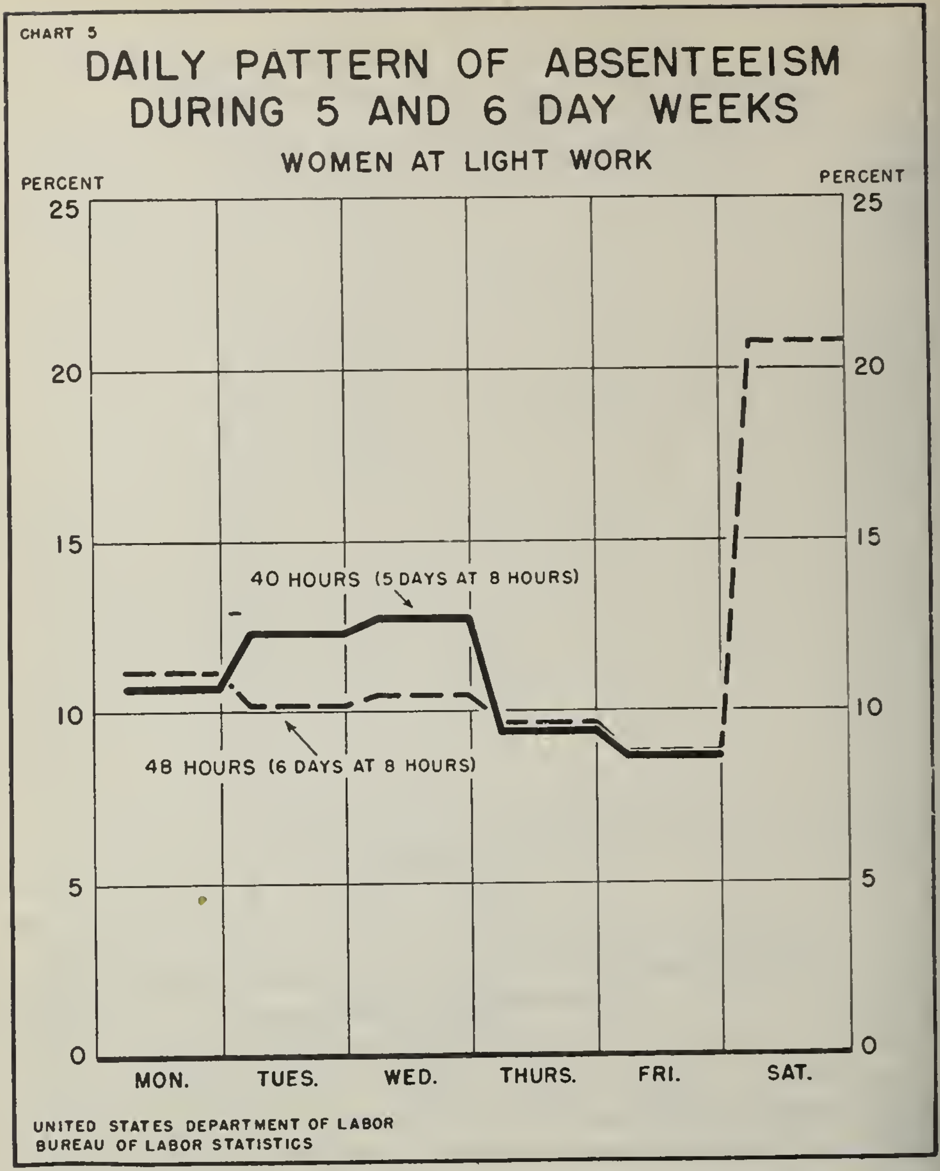
When a 7-day week was worked, absences were more frequent during each of the 6 days of the week than during the corresponding days of the 6-day week—but lowest on Sunday for the women in case study 28. Quite understandably, the operators worked Sunday at double pay, and took time out on some other day of the week, preferably Monday.

The men in study 24, however, were absent more frequently on Sunday during the 7-day week, with the second-highest absence rate on Monday.

The patterns for the 9-hour and 10-hour days are about the same as for the 8-hour days, except that absenteeism on Saturday, the sixth day, reached much higher levels for men than during the 8-hour day. Except for case study 75, all of the studies shown concern men.

The men in case study 7 had the highest rate, 5.8, on Monday during the 5-day week, with daily hours at 10. But when a sixth day was added, at 8 hours, for a 58-hour week, the high point shifted to Saturday—with 11.0

CHART 5



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

percent. For the rest of the week, the absence rates under the two schedules are very similar. The difference comes on Saturday.

Similarly, absenteeism for the men in case study 77 reached 17.5 percent on Saturday, and 10.4 percent in case study 75.

Because women were limited by State laws from working long hours, and because management quickly discovered that long hours were not advisable even when possible, few women operators were found at the higher levels of daily and weekly hours. The daily pattern for one group at 10 and 11½ hours is shown for case study 75. It will be noted that the time lost because of absenteeism was lower during the 10-hour-day schedule than during any corresponding day under the 11½-hour schedule, even though the latter involved a 5-day week and provided a 2-day week end. During the 6-day week, as in other cases listed, absenteeism was highest on Saturday.

CHAPTER IX.—Effects of Introduction of Wage Incentives

During the war there was considerable agitation for a more widespread use of wage incentives as a means of increasing output. Such schemes could effect such results only when the pace of operations was controlled by the worker either in whole or in part. As pointed out in connection with individual case studies, when the pace was controlled entirely or primarily by the machine, then output tended to increase proportionately with increases in hours, because nonproductive time—getting ready, cleaning up, etc.—was spread over a longer workday, and offset the lower efficiencies of workers.

To increase output by inducing workers to speed up requires two basic conditions: (1) that the original pace, without the use of the incentive, is moderate or slow and can be speeded up, and (2) that the work is such that a faster pace can be maintained over the schedule of hours to be worked, so that it will not be vitiated by a gradual or sharp dropping off in efficiency or a sharp rise in absenteeism.

The most graphic demonstration of the effect of the introduction of a wage incentive system is provided by case studies 1 to 4. These four groups of men worked in a nonferrous-metal foundry in which work was both hot and heavy. Working conditions were noisy, smoky, and quite hazardous. All of the workers studied were males, and about 60 percent of them were Negroes, many of whom had developed into highly skilled operators through years of service with the company.

The records of about 200 men were studied. These men were classed into 3 groups, which differed in wage incentives and weekly hours. Group 1 included about 45 men on the floor-mold-department day shift. Although weekly hours were reduced by the dropping of Saturday work, the men did not go on piecework, but continued at day rates. Group 2 included two subordinate groups consisting of (a) about 80-90 selected men in 13 crews on the day shift of the floor-mold department, who worked at time rates until November 1942, when they went on piecework simultaneously with shortening the workweek, and (b) a group of about 15 men on the night shift of the squeezer department, whose changes in weekly hours and methods of wage payment were the same as those for the selected men on the floor-mold day shift. Group 3 included about 35 selected men on the day shift in the squeezer department who went on piecework in November 1942, but whose scheduled weekly hours remained essentially unchanged—about 58 per week.

Group 1 therefore illustrates the performance of a group of men who remained on day work throughout, without any wage incentive, but experienced a reduction in weekly hours. Group 2 illustrates the performance of men who experienced both a change in method of wage payment and a change in weekly hours. Group 3 illustrates the performance of men who had a change to a wage incentive but no change in scheduled weekly hours.

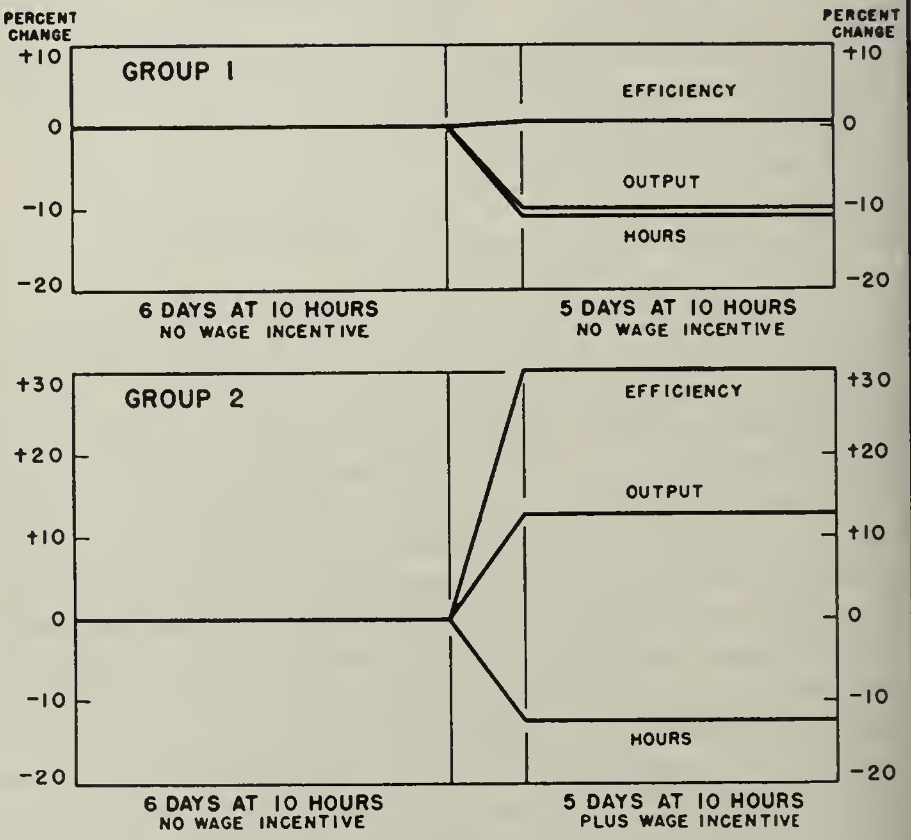
1. Without the stimulus of an incentive wage, a reduction in average weekly hours from about 60 to about 53 resulted in no appreciable change in hourly efficiency and, consequently, brought about a proportionate reduction in total output.

As already indicated, this finding results from an analysis of the performance of a group of about 45 men in the floor-mold department. For a number of reasons, principally because records were not so adequate as for the men on piecework, it was not possible to develop for this group the same production yardstick as for the selected group. A fairly reliable though rougher method of comparison was obtained by computing an average number of man-hours per casting, even though the types of castings varied throughout the entire period studied. The assumption that the differences in castings

CHART 6

EFFECTS OF INTRODUCTION OF WAGE INCENTIVE AND SHORTENING OF WEEKLY HOURS

DAY SHIFT FLOOR MOLD DEPARTMENT OF A FOUNDRY



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

would average out during the two levels of hours used for comparison was justified by the fact that the plant remained at essentially the same type of production throughout the period.

As is apparent from table 19, a reduction in weekly hours of nearly 11 percent resulted in a reduction in output of 10 percent. The difference of nearly 1 percent is attributable to the fact that efficiency increased slightly, by about 0.7 percent. This increase may have been the result of the elimination of Saturday work, or the contagious effect of the faster pace set by the men on piecework, or both. In any case, it was practically negligible in its effect on total output.

TABLE 19.—*Comparative performances on foundry work at various weekly hours*

Period	Average weekly hours	Scheduled days per week	Efficiency rate	Indexes of —			Incentives
				Average weekly hours	Efficiency (output per man-hour)	Total output	
Floor-mold department							
Nonselected men:							
2/42–10/42 (exclusive of July-September)	59.7	6	100.2	100.0	100.0	100.0	None
11/42–1/43 (transition period)	53.7	5+	94.3	90.0	94.1	83.5	Do.
2/43–5/43	53.3	5+	100.9	89.2	100.7	90.1	Do.
Selected men:							
1/42–10/42 (exclusive of July-September)	59.7	6	89.8	100.0	100.0	100.0	Do.
11/42–1/43 (transition period)	57.1	5+	100.1	95.6	111.5	110.4	Piecework
2/43–5/43	52.4	5	117.0	87.8	130.3	112.7	Do.
Squeezer department							
Selected men, day:							
1/42–11/42 (exclusive of July-September)	58.4	6	96.3	100.0	100.0	100.0	None
12/42–5/43	55.3	6—	101.9	94.7	105.8	102.7	Piecework
Selected men, night:							
1/42–11/42 (exclusive of July and August)	58.2	6	97.0	100.0	100.0	100.0	None
12/42–1/43 (transition period)	55.9	5+	100.3	96.2	103.3	110.5	Piecework
2/43–5/43	50.4	5	108.0	86.8	111.2	103.3	Do.

The fact that average weekly hours fell only to about 53 (instead of about 50), after the dropping of Saturday work, was due to the fact that the men remained at the end of each day to complete the molds already started.

2. A sizable reduction in weekly hours because of the elimination of Saturday work, coupled with the introduction of the incentive wage, resulted (a) in a sharp increase in hourly efficiency and (b) in a total-output level higher than that experienced at the longer weekly hours.

Both the day shift in the floor-mold department and the night shift in the squeezer department illustrate this point.

The floor-mold group consisted of 80 to 90 men. Because these men were on piecework, it was possible to compute an adequate measure of efficiency for them, both for the period during which they worked at piece rates as well as for the preceding period at day work. In judging the performance of this group, it is pertinent to bear in mind that these men represented the more experienced group on the day shift, and that they were put on piece rates for precisely that reason.

If the performance level during the 60-hour week is taken as a base, the reduction of weekly hours of about 12 percent finally resulted in an increase of efficiency of 30 percent and in total output of nearly 13 percent. In other words, even though the men did not work on Saturday, they produced 13 percent more during the shorter week.

The performance of the 15 men on the night shift in the squeezer shop was less spectacular, but still in the same direction. By dropping Saturday work, average weekly hours were reduced from 58 to about 50, or about 13 percent. Efficiency went up 11 percent, however, with the result that total output increased by more than 3 percent. As in the case of the floor-mold day-shift men at piecework, the total output of the squeezer-shop night-shift men was higher during the shorter workweek than it had been during the longer workweek.

The difference in the relative performances of the day-shift and night-shift men discussed here may be explained by the fact that the men on the day shift had longer seniority and consequently represented the "older hands" or better-skill group. The day shift also had the advantage of more supervision and more "long-run jobs." The night shift cleaned up orders started by the day shift and consequently could not maintain so steady a production stride.

It is also likely that the night men were not able to put forth as much sustained effort because of their habit of sleeping upon their return from work and of being up and around for several hours before going to work. The day-shift men, on the other hand, had their leisure hours after the day's work was over.

3. The introduction of incentive wages, but with the longer workweek essentially maintained, resulted in a slight increase in efficiency and a small increase in total output.

As chart 7 indicates, average weekly hours for the approximately 35 men studied on the squeezer department's day shift actually were reduced from about 58 to 55. The reasons for the apparent 5-percent reduction were that some of the men did not work on Saturday, and that occasionally the entire group worked only 6 or 6½ hours on Saturday instead of the customary 8. As the crews which did not work the sixth day kept changing—apparently because of some system of rotation—the group had to be studied as a whole.

For all practical purposes, however, scheduled hours may be considered as having remained essentially unchanged. The changes in efficiency and output, although influenced to some extent by periodic stoppages on Saturday for a small part of the group, were due primarily to the introduction of the incentive wage. Efficiency went up by nearly 6 percent, and total output by nearly 3 percent.

The introduction of piecework caused the men to speed up, but the increase in pace was not nearly so great as when the incentive system was coupled with a shorter workweek.

4. With the introduction of an incentive system, the reduction in weekly hours caused by the dropping of Saturday work is estimated to have resulted

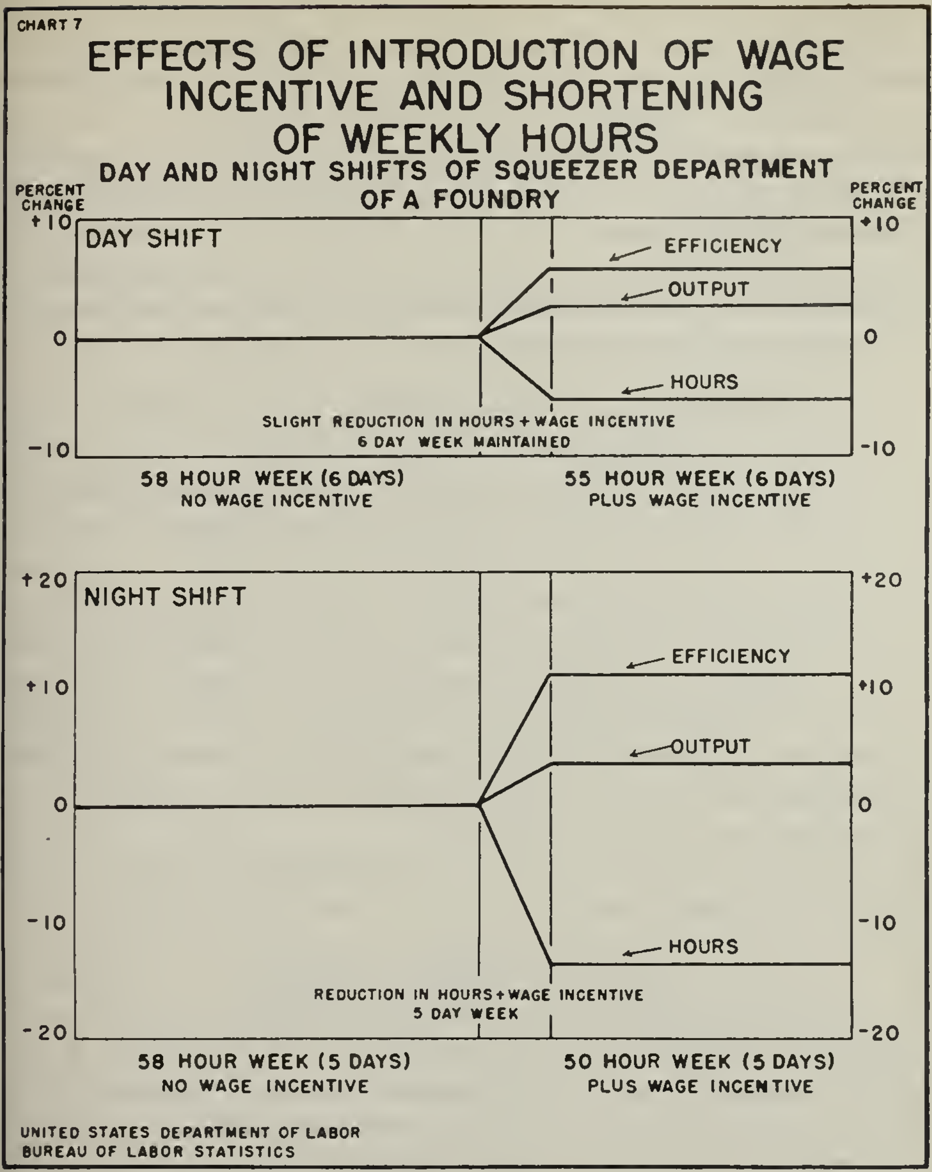


CHART 7

EFFECTS OF INTRODUCTION OF WAGE INCENTIVE AND SHORTENING OF WEEKLY HOURS

DAY AND NIGHT SHIFTS OF SQUEEZER DEPARTMENT OF A FOUNDRY

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

in an increase in efficiency of 24 percent and in output of 10 percent above the levels which prevailed at the longer hours.

This conclusion follows from the comparison of the day shifts of the floor-mold and squeezer-shop departments. Both groups went on piecework at the same time. Both were composed of experienced men who had been with the company for some years. The principal difference between them was that the men in the floor-mold department stopped working on Saturday, while the men in the squeezer shop continued. Although the methods of preparing the molds differed, working conditions for the two groups were identical. Had Saturday work been stopped for the squeezer-department men, there was no reason why their efficiency could not have spurted like that of the floor-mold men.

The net effect of the reduction in hours is found by obtaining the differences between the performances of the two groups. The introduction of piecework resulted in an increase in efficiency of the squeezer-department men of about 6 percent. Assuming that this is a fair measure of the effect of the incentive wage in itself, the difference between this rate of increase and the 30-percent rate for the floor-mold men leaves an increase of 24 percent as the net result of the reduction in hours. Similarly, the difference between the increases in output of about 13 percent and 3 percent (i. e., 10 percent) measures the increase in output which may be attributed primarily to the effect of the shortened hours.

Although the shorter hours appear to have been the more decisive of the two factors involved, it is clear that there would have been no increase at all in the absence of the incentive-wage system.

Absenteeism as Related to Hours and Earnings

The records of the foundry did not permit a detailed, or even a comprehensive, analysis of the absenteeism problem. It was possible, however, to gauge for each of the three shifts studied the relative performance under the different patterns of working hours and wage determination.

By assuming that the maximum number of workers on the pay roll during any one day of a week represented the total crew supposed to be at work on each working day of the week, it was possible to obtain a measure of absenteeism by deducting from this figure the number of men who actually worked each day. Although this is not a highly accurate measure of absenteeism, it appeared to be the best possible and did reveal significant results for the periods analyzed.

The day shift in the floor-mold department experienced a sharp drop in absenteeism when hours were reduced by eliminating Saturday work. Absences decreased by more than a third from an index of 100 during the period of long hours to about 61. During the remainder of the period at shorter hours, but with more than half of the department on piecework, absenteeism increased to an index of about 79.

The same general trend, but with greater differences, appeared in the averages for the night shift in the squeezer department. There, as was the case for a part of the day shift in the floor-mold department, hours were reduced and the entire crew went on piecework. The first result of the change was a drop in absenteeism to half of what it had been at the level of longer hours. Thereafter, however, the index rose to 110, or 10 percent above the level for the longer workweek.

The day shift of the squeezer shop, it will be recalled, stayed at essentially the same hours, but went on piecework. After the introduction of piecework, absenteeism was higher by 25 percent.

The data suggest some interesting conclusions. The first result of the shortened workweek was a decided drop in absenteeism. The subsequent rise in absenteeism appears to be connected with increased earnings. This conclusion gains credence from the fact that the absenteeism level during the last period studied was highest for the day shift of the squeezer shop (which underwent no change in hours) and was higher for the squeezer-shop night shift (with all men on piecework) than for the entire day shift of the floor-mold department, with only about two-thirds of the crew on piecework. (Unfortunately it was not possible to obtain a separate measure of absenteeism for the two groups on the day shift of this last department.) The data indicate that—

(1) Absenteeism increased very appreciably with the introduction of piecework and the retention of a long workweek.

(2) The effect of increased earnings was to increase absenteeism even after hours had been shortened.

The fact that increased earnings were a material inducement toward absenteeism was freely admitted by the workers. In one instance, for example, a worker commented that he had had several "very good weeks," and he thought he and his "old lady" would take a "little trip for most of next week."

Absenteeism was very high on Saturday during the 6-day week, and it was also high on Monday.

The main reason for the high absenteeism on Saturday appears to have been the fact that pay day was on Friday. Attempts by management to shift pay day to Saturday were resisted by the union, which insisted that the men be given an opportunity to cash their checks, which was difficult to do after working hours. To meet this objection, management invited into the plant a check-cashing service on Friday. This service cost 10 cents per check, but made it possible for the workers to cash their checks without leaving the plant. The experiment met with so little response from the workers that it was given up after a few weeks.

Effects of Changes in Hours on Plants With and Without Wage-Incentive Systems

The preceding study was told in considerable detail because it represented an instance in which it was possible to gauge the difference caused by the introduction of the incentive system itself. It is also pertinent to note differences in the relative performances of worker groups under various types of incentive systems, or under straight day work.

The experiences of 18 worker groups are shown in table 19. These cases were selected because they involved no extraneous factors that might leave the measures of performance open to question. For example, the comparisons shown are, for each study, either entirely within or entirely without the war period. They involve no problems of Sunday work, reductions in force, managerial changes to improve the flow of production, etc.

In the first three of these studies, the men worked at straight day rates, and without any kind of wage incentive. In each case, output changed directly in proportion to the change in hours, indicating that the same pace was maintained regardless of hours. As output for men at piecework or other forms of direct incentives usually increased proportionately less than hours when they were raised substantially, the conclusion seems warranted that the slower pace which characterized the longer schedule for the men at straight day rates also prevailed during the shorter schedule. In short, operators who stood to gain nothing by working fast would not do so. Consequently, it was possible to increase hours—within reasonable limits—without impairing output. An hour's output resulted for each additional hour worked.

All of the cases shown under group incentive systems involved moderately heavy work. In only one case (9) was the level of efficiency—which reflects average hourly output per hour worked—as good at the higher level of hours as it had been at the lower level. The fast pace maintained during the shorter work schedule could not be maintained during the longer hours. In some instances, the drop in efficiency was drastic in spite of the fact that the workers were concerned with the production of shells (studies 20 and 21). Under group incentive systems, however, the pace of the less efficient workers becomes the limiting factor.

Ten case studies in table 20 reflect experience under individual incentive systems, either piecework or bonus systems. As a rule, all output in excess of a set standard was paid for in full.

TABLE 20.—*Relation of performance at various schedules of hours and incentive systems*

Case study and type of operations	Incentive system	Change in scheduled weekly hours —		Percent change in —		
		From	To	Hours	Efficiency	Output

70 — Moderately heavy — rubber industry	. do	40	48	+20.0	+1.6	+21.4
71 — Moderately heavy — rubber industry	.. do	40	48	+20.0	+1.9	+20.8
72 — Light operations — rubber industry	... do	40	48	+20.0	+.8	+20.2
74 — Moderately heavy — rubber industry	....do	40	48	+20.0	+3.9	+22.8

In case study 7 in which the operating pace was controlled primarily by machines, the change in hours was matched by a nearly equal increase in total output. Where the speed of machining and assembling operations rested primarily with the operators, as in case study 35, efficiency could not be maintained during the longer hours. The pace slackened.

The strippers of tobacco leaves (study 45) tried to earn as much in 40 hours as they formerly had in 48, and just about succeeded. To do it, however, they had to speed up their pace during the shorter schedule by nearly 20 percent.

The women in case study 58 could not do it. Even though they worked faster during the 40-hour schedule, they could make up only about one-third of the earnings they had lost through the reduction of 8 hours in the workweek.

Studies 67, 69, 70, 71, 72, and 74 show an opposite result: in each case the lengthening of the workweek, usually from 40 to 48 hours, resulted in a slightly better efficiency during the longer hours. Observations of the workers during the longer schedules, however, indicated that the pace of these operators was moderate, and was considerably slower than the pace observed in other operations in which the physical demands of the job upon the workers were similar. It follows that the pace under the shorter schedule could have been faster. Regardless of the reason for the speed of the work pace, it is obvious that individual incentive systems do not ipso facto mean that operators work at their optimum efficiency. Where the pace is moderate, therefore, output can be increased in direct proportion to the increase in hours, even though these are raised to 55, and perhaps to 60. This appears to be particularly true of operations which allow the operator considerable initiative and are not strictly routinized and monotonous. Although it was not possible to study such situations, instances were found in which the production of tool makers held up well under 60- and 70-hour weeks.

Limitations on initiative—Some of the studies cited seem to suggest deliberate production pacing by operators; management at times reached the same result by limiting the amounts workers could earn. In case study 8, workers definitely held their earnings to less than $1 an hour under several of the schedules studied because they knew that their piece rates would be cut if they exceeded this amount.

Similarly, the workers in study 19 held down their earnings—and output—because of a 30-percent ceiling. In another survey of men producing shells—not included here for various reasons—a 25-percent ceiling held production in each of a great variety of operations to a fixed level. The records showed exactly the same number of units produced, day after day, month after month.

Just what induced management to impose such ceilings, it was sometimes hard to see. With quality inspection to guard against defective production, it would seem that the higher the output, the lower the over-all unit cost. There is, of course, the danger that haste may increase spoilage which cannot be reclaimed. But that fact, one may presume, ought to be established through actual experience rather than by managerial fiat—as it was in the three cases cited.

CHAPTER X.—Prewar and Postwar Performances

The charge has frequently been made that workers performed less efficiently after the war than before or during the war. One might expect that the fact that we were in the war would have a perceptible influence on the will to work. A reading of the case histories will reveal case after case in which—for the same or even higher hours—worker performance improved during the war. In many of these cases, management explained this as the direct result of our participation in the war. Millions of workers had sons or other relatives in the war and were determined to do their part.

A let-down after the end of the war might well have been expected. The shot-in-the-arm which the war supplied was gone. Furthermore, many plants cut back on their operations and reduced not only hours, but the number of workers as well. Being human, workers could not be expected to continue to work at high speeds if that meant working themselves or others out of jobs.

Table 21 presents comparisons between efficiencies at similar prewar, war, and postwar schedules. The last two cases shown on the table, 78 and 29, illustrate the point just made about the effects of reductions in force. In both cases, the cut-back in hours was accompanied by decreases in efficiency because of the simultaneous sharp reduction in force.

TABLE 21.—*Comparison of efficiences during comparable prewar, war, and postwar schedules*

78	....	48	35	....	100.0	96.7	....	—3.3	
29	....	58	50	....	100.0	94.6	....	—5.4	....

The other studies listed on the table demonstrate two points: (1) that wartime efficiencies were generally higher than prewar efficiencies in spite of longer hours; and (2) that, where comparison was possible, the efficiency during the postwar week (after an adjustment period) was substantially better than it had been during the same work schedules during the prewar period studied.

Frequently the higher efficiency during the war was offset in part, and sometimes entirely, by increased absenteeism during the longer work schedules. The data indicate very definitely, however, that men and women worked harder, particularly when stimulated by wage incentives. The efficiency indices during the war period were superior to those of the prewar period in every instance in which comparison was possible.

In some cases, the better wartime performance failed to hold up after the war ended. In spite of reductions in hours, the efficiency indices in cases 67, 69, 70, and 73 decreased from the wartime levels. In most instances, however, the reverse was true. In 15 cases out of 20—if the two reduction-in-force examples are excluded (78 and 29)—postwar performance was superior to war performance. The reasons for this, undoubtedly, were (1) that it was possible to maintain a faster pace because of the shorter hours, and (2) that workers wanted to work harder so as to make up some of the pay they lost when hours were curtailed.

Of still greater interest, however, are the postwar—prewar comparisons. In nine case studies it was possible to compare the efficiency during a postwar schedule with an identical prewar schedule. The postwar performance was always better, and the improvement in efficiency was 10 percent or better in every instance but one (study 73), for which it was 6.9 percent. Generally, the increase in average hourly output was about 15 or 16 percent, and went as high as 19.3 percent (study 49).

No data are available to indicate the extent to which these results reflect general industry experience. They are presented here as findings based on careful analyses of industry records. They were not selected to prove any particular point. It is significant, however, that they all point in the same direction.

CHAPTER XI.—Methods

A.—Collection of Data

As indicated at the outset, one of the most difficult features of this survey was to find plants with the changes in hourly schedules and type of operations and records that would lend themselves to the basic purpose of the study.

Having located a cooperative plant in which at least two substantially different levels of hours had been worked over a period of not less than 6 months each, and having determined that the available records could be used, the next step was to select the group of workers to be studied. That frequently proved to be a stumbling block because of the great turn-over during the war.

Care was taken to select for study a group of workers as homogeneous as possible. New and inexperienced workers were excluded. Where the workers in the plant or department—depending on which was being studied—did not have the same daily and weekly hourly schedules, only those workers were selected for study who could be grouped into similar patterns of hours. Similarly, data were obtained separately for shifts, and differentiated by sex.

The period to be covered under any one schedule was another problem. Obviously, it had to be long enough to permit the effect of the schedules being studied to emerge clearly. It was apparent after the first two or three studies—for which, fortunately, continuous data were available over a period of years—that a shift to a new schedule did not result in an immediate change to readily ascertainable new patterns of efficiency, absenteeism, and output. It was found, for example, in case study 1, that it took about 4 months for the patterns of the 50-hour week to emerge clearly after a change from a 60-hour schedule. Similarly, in case study 7, the efficiency of the 40-hour week was maintained for 3 months after weekly hours had been raised to 50, and then decreased sharply to a lower level. Then, as hours were increased still further to 58, coincident with our entry into the war, efficiency not only was maintained, but actually increased. This new level held for nearly 6 months. At that point, however, fatigue finally forced a drop in efficiency to a level below that which had characterized the 50-hour week.

In this case, the work was primarily machine-paced and workers were afforded some rest—at least a partial relaxation of effort—while the machines performed. It was expected that in operator-paced work done at considerable speed, the transitional periods would not be nearly as long. But it was clearly recognized that the selection of any 1-, 2-, or 3-month period, subject to the possible vagaries of transition, would not be satisfactory. The effort, therefore, was to cover a year's period under each schedule. The wisdom of this decision was apparent in the analysis of the data obtained in subsequent studies, when considerable deviation from the nominal work schedules was found for considerable numbers of workers.

It was believed, furthermore, that it was essential to cover longer periods where the groups of workers were small so as to eliminate the effect of erratic individual experiences. Where the group of workers was large, it was believed safe to cover shorter periods of time.

In nearly every study, the group of workers studied consisted of selected individuals. As already indicated, these were selected for comparability of operations under the schedules to be compared, consistency in adhering to these schedules, work experience, and similar factors. The findings for the group actually represent the composite experiences of individuals for whom data were obtained. In the few instances in which only group data were available, the data were used only after it had been ascertained that the composition of the group had either been constant, or that turn-over had been small and that operators who had left had been replaced by others of approximately the same degree of experience. (For example, case study 8.)

Minor changes in hours were excluded from the survey except as they were incidental to more substantial changes. For example, a plant was not studied if hours changed from 52 to 54 per week. It was studied if the change involved shifting from an 8-hour day to a 9- or 10-hour day, or if weekly hours were increased by at least 5 or 6. This might be accomplished either by increasing daily hours, or adding an additional workday, or both.

The periods selected represented either increases in hours or, late in the war or after it had ended, decreases in hours. In a number of plants it was possible to trace the data back so as to obtain comparable data for prewar, war, and postwar schedules, thus spanning a period of 4 or 5 years.

As far as possible, periods were selected to cover a year or more under each schedule. Where the various schedules were in effect for a shorter period, care was taken to select the same months in the year so as to rule out the effects of temperature, holidays, and of such outside attractions as hunting and fishing seasons.

Data were obtained for each selected worker on hours worked, volume produced, time lost, and injuries. Turn-over could not be taken into account in most cases except as it applied to the entire staff of the plant or department. For the relatively small group of men or women that satisfactorily met the rather stringent requirements of the methods used for selection, turn-over data would have been rather meaningless.

After the statistical processing and analysis of the data, which was done by the Washington staff, a copy of the report and findings was sent to the management of each plant studied, in part to invite criticism or comments, and in part to appraise management of the results of the survey. In that way, the cooperation and assistance by management were at least partially repaid. (It may be added, parenthetically, that some of these findings were at complete variance with the opinions expressed by management during preliminary discussions.)

It should be added also that, in every instance, the data were selected and transcribed by members of the Bureau's staff and that the data are substantially comparable throughout the survey.

B.—Statistical Methods

Hourly schedules.—The data concerning scheduled hours consisted either of actual schedules, or data on hours or days worked, and hours or days absent for each worker. Where possible, data were gathered on a daily basis. Where this was not possible, weekly data were used.

In the analysis, the schedule for each workweek was determined by dividing the total of all days worked and lost by the number of workers so as to obtain a measure of the average hours actually scheduled. Weeks in which this average fell substantially below or substantially exceeded the nominal schedule were excluded. In checking back with the plant, it was found frequently that the variation was caused by a shortage of material or an attempt to break a temporary bottleneck in production. In any case, if the variation was more than about 2 hours, the data for the week were excluded from the analysis. Sometimes it was possible to rule out the data for individual workers if the analysis clearly indicated that their schedules for the particular week were considerably in excess or below the basic schedule for the group. Thus, for example, the performance of a man who worked 60 hours was excluded when the rest of the group worked 48 or 50 hours. If his performance during the next week fell markedly below his usual performance either in output or work attendance (reflecting the effects of the preceding week), the data for him for this next week were also excluded. In short, every attempt was made to make the findings as accurate as possible and to remove distorting factors.

The total hours worked by any one survey group was obtained by adding up the hours worked by the individuals of the group.

Absenteeism.—Absenteeism is defined as worktime lost because workers did not show up or stay on the job when they were scheduled to work. The absence could have been caused by illness of the worker or of some member of his family, by accident, or by any other personal reason. Scheduled vacations or time lost because of lay-offs, however, were not included because workers involved were not scheduled to be at work. Periods containing strikes were excluded.

The percentage of scheduled worktime lost was computed by the formula:

$$\text{Absenteeism rate} = \frac{\text{total employee-hours lost}}{\text{total employee-hours scheduled}}$$

Where absenteeism was reported in days, the days lost were converted to scheduled hours lost.

Obviously, the hours actually worked and the hours lost through absenteeism added up to 100 percent of total employee-hours scheduled to be worked.

Efficiency.—Efficiency is the average hourly output per hour actually worked. Hours lost through absenteeism were excluded in this computation. What was wanted was a measure of average performance under any one schedule of hours while operators were actually on the job.

The basic formula for efficiency was:

$$\text{Efficiency} = \frac{\text{total weekly output}}{\text{total hours actually worked}}$$

The methods to obtain this result varied considerably, however, because of the types of records available in the plants studied.

(a) Where no records of output was kept, but where piecework earnings were recorded by the plant, efficiency was measured by average hourly earnings. The base-period earnings were used as an index of 100, and variations in earnings were computed from this base.

Involved in this problem was the complication of overtime pay. This was resolved by increasing hours actually worked to the total hours which were paid. For example, if a man worked 48 hours and received 1½ pay for hours above 40, he actually was paid for 52 hours. In the computation of hours earned, his time was figured at 52 rather than 48 hours.

In a few instances, notably case study 8, the situation was complicated further by periodic increases in the basic hourly rates which were used to establish piece rates, and by a deliberate loosening of time standards, so as to increase the take-home pay of workers when wage increases were forbidden. The first of these adjustments was simple to make because the percentages of increase and the times they went into effect were definitely known. The second could be made only where the loosening of standards came at one time, or during a short interval during which all rates were restudied. But where the data indicated a gradual loosening of standards over a long period of time, the data could not be used.

This applied, incidentally, not only to piece rates but to all other measures of performance based on time standards rather than on actual number of units produced.

(b) When the actual number of units produced was reported, the problem was simple. The formula used was:

$$\text{Efficiency} = \frac{\text{total units produced}}{\text{total employee-hours worked}}$$

(c) Where time standards had been established, the basic data recorded both the hours actually worked by each individual and the total number of standard hours or minutes of production. A variety of systems were encountered, but basically the data were the same regardless of the degree to which workers were compensated for the time they saved from the standard time. In these cases, the formula used was:

$$\text{Efficiency} = \frac{\text{standard hours produced}}{\text{actual hours worked}}$$

(d) A variation of this formula was used when the number of unit hours produced were reported in relation to the number of hours of output called for by the standard. In this case the formula was:

$$\text{Efficiency} = \frac{\text{number of units produced}}{\text{standard number of units required for hours worked}}$$

(e) In a few instances, the company computed efficiencies by one of these methods (except (a)) for purposes of its own. Where such efficiencies were available, the computation of efficiency consisted simply of averaging these efficiencies for the selected workers over each schedule period.

Output.—Because of the variety of methods used to compute efficiency, a formula was developed for the output computation which could utilize the rates already computed for efficiency and absenteeism. Obviously, output is the composite result of average hourly output and the number of hours actually worked. The difference between hours scheduled to be worked and hours actually worked is the number of hours lost because of absenteeism. Following this line of reasoning, the output formula used was:

Output = Scheduled hours × (100 percent — percent of time lost through absenteeism) × efficiency.

A brief example will indicate the practical application of the formula. Suppose efficiency, in relation to the selected base, was 95 percent, time lost through absenteeism was 10 percent, and scheduled hours were 54 per week. According to the formula, the index of output was:

$$\text{Output} = 54 \times .90 \times .95 = 46.17$$

Suppose that during the 40-hour week period used as a base for both changes in hours and efficiency, the efficiency index was 100 and absenteeism was 6 percent. Then, by formula—

$$\text{Output} = 40 \times .94 \times 1.00 = 37.60$$

Comparing the two schedules, we find that the increase in scheduled hours was $\frac{54 - 40}{40}$ or 35 percent. Similarly, the increase in

$$\text{output was } \frac{46.17 - 37.60}{37.60} \text{ or } 22.8 \text{ percent.}$$

The obvious conclusion is that an increase of 35 percent in scheduled hours (from 40 to 54) resulted in an output increase of 22.8 percent. Roughly, 2 hours of output—at the performance level at 40 hours—were gained for each 3 hours worked between 40 and 54.

Injuries.—In computing the frequency rate of work injuries, the standard formula was used:

$$\text{Frequency rate} = \frac{\text{number of injuries} \times 1{,}000{,}000}{\text{total number of exposure hours}}$$

This formula yields the average number of injuries per million employee-hours of exposure.

CASE STUDIES

1: Workweek of 60 hours vs. one of 50 hours, no wage incentives; hot and heavy, man-paced floor-mold operations in a nonferrous metal foundry; men.

Work was devoted entirely to the production of castings for airplane motors, superchargers, and similar materials essential to the war effort. After the hand-made molds were dried and hardened through a baking process, they were sent to the floor-mold department, which produced the heavy castings. Work was generally done in crews consisting of six men each.

The crew was led and the pace set by a finisher or molder who assembled the cores or supervised the assembly of the larger molds, inspected and repaired completed molds, and generally was responsible for the operation of his crew. The metal was then poured. The "shake-out" and "knock-out" men moved the cooled castings (still in the molds) by crane to the shake-out section where the air vibrator loosened the sand sufficiently to allow each casting to be freed. The knock-out man's particular task was to guard the casting against damage during this process.

The work was heavy, hot, smoky, and entirely man-paced.

Working conditions.—The noise in the foundry was so great that frequently the warning signals of cranes or trucks could not be heard by the workers. the volume of fumes emitted from the baking ovens and from the exhaust of plant trucks was considerable. The chemically treated sand, when baked into molds, gave off a searing smoke which made the eyes smart and parched the throat. A large amount of dust was created by sand. The temperature was always high in the vicinity of some operations, particularly so during the summer months. Air vents were insufficient to cope with the amount of dust, fumes, and heat existing in the foundry. Lighting was exceptionally good. The shop lacked showers and lunchroom facilities. Washroom facilities met only minimum requirements. On the whole, working conditions were noisy, smoky, and quite hazardous.

An average of 45 minutes a day was spent by the men in waiting for the metal to be poured.

Industrial relations.—During the nearly 1½ years covered by the survey, the relations between labor and management were bad. This resulted largely from the company's policy of paying wage rates somewhat lower than prevailed in the area. Contemplated raises were prevented by the wage freeze in 1942. A majority of the operators in the plant were Negroes.

Wage incentives.—Workers received straight hourly pay during the period studied. There were no wage incentives. The survey covered the performance of a group of about 45 men on wartime schedules of 60 hours per week (6 days at 10 hours) and subsequently one of 50 hours (with some overtime) during which Saturday work was eliminated. Under each schedule daily hours remained at 10. The workers studied belonged to a nonrotating day shift.

The period covered by the survey extended from February 1942 through May 1943.

Safety.—Working conditions were hazardous, and not much attention was paid to safety. Housekeeping was bad, and there was a great deal of congestion and crowding. Many of the operators did not wear adequate protective clothing and goggles, and there was little attempt to make them comply with basic safety regulations.

FINDINGS OF STUDY

Efficiency remained practically unchanged when workdays were reduced from 6 a week to 5, but with the retention of the 10-hour day. The change in weekly hours brought about an increase in average hourly output of only 0.7 percent.

The pace of the workers—on straight day work and without a wage incentive—remained essentially the same under both weekly schedules.

Absenteeism could not be measured for the group of workers represented in this case study. The data did not permit a factual determination of who was scheduled to work on specific days. By making some assumptions, however, it was possible to arrive at approximations of time loss for the entire department, of which the group represented here composed about one-third. The rates are undoubtedly understatements in view of the nature of the work, the type of workers involved, and the difficulty of getting good work attendance on Saturday and Monday.

The relative estimates indicate that the decrease in workdays from 6 to 5 decreased time lost from work slightly, from a level of about 3.8 percent to one of 3 percent.

Output varied almost directly with the change in hours.

2: *Workweek of 60 hours with no wage incentives* vs. *one of 50 hours with individual wage incentives; floor-mold operations in a nonferrous metal foundry; men.*

The men belonged to the same shift of floor-mold workers as those discussed in the preceding case study. Working conditions were the same as those already discussed.

The group studied consisted of about 80–90 men in 13 crews on the day shift of the floor-mold department. During the scheduled 60-hour workweek (6 days at 10 hours) these men were on straight hourly rates. But when hours were reduced to 50 per week by dropping Saturday work, a piecework system was introduced simultaneously.

FINDINGS OF STUDY

Efficiency.—Elimination of Saturday work, coupled with the introduction of the incentive wage, resulted in a sharp increase of 30 percent in hourly efficiency. Total output was 13 percent higher than it had been during the longer workweek. Inasmuch as the remainder of the day shift continued to work without a wage incentive, the marked difference in performance between the men covered in this and the preceding case studies may be attributed largely to the introduction of the wage incentive. It is questionable, however, whether the change would have been as marked had the hourly schedule remained at 60 per week. (See case study 4.)

Absenteeism, as indicated in case study 1, was difficult to measure. The data indicate, however, that the immediate effect of the curtailing of the workweek was a sharp drop in unauthorized absences from work. This was an expected result, as attendance on Saturday had been poor at the longer work schedule.

After a transitional period of several months, however, absences increased again, although remaining below the level that had prevailed during the 6-day schedule. Management believed that this rise in absenteeism was directly related to the greater take-home pay of the men on piecework. The explanation advanced was that many of the men had recently moved up from southern states and were earning far in excess of what their customary standard of living required.

3: *Workweek of 58 hours, night shift, with no wage incentives* vs. *one of 50 hours, with individual wage incentives; hot and medium-heavy, man-paced, squeezer-mold operations in a nonferrous metal foundry; men.*

This is the third group of men studied in the foundry described in case study 1. This department differed from the floor-mold department discussed in the two preceding cases in two important respects: (1) The castings were not as heavy; (2) the smaller molds in the squeezer department were hardened through compression ("squeezed") and were not baked. Working conditions were essentially the same as those described in case study 1.

As the moldings were smaller, a crew of two men usually performed all the necessary operations.

The group of 15 men studied were on the night shift during the entire period surveyed, from January 1942 through May 1943. During the 58-hour workweek, consisting of 5 days at 10 hours and Saturdays at 8, these men worked on straight hourly rates. With the elimination of Saturday work and a consequent reduction in weekly hours to 50, they went on piecework.

INDINGS OF STUDY

Efficiency.—The reduction in weekly hours from 58 to 50, by the elimination of the 8-hour Saturday, together with the introduction of the wage incentive, resulted in an increase of 11 percent in average hourly output. The total output level during the shorter workweek was about 3.3 percent higher than that experienced at the longer weekly hours. These findings parallel those of the preceding case study, although the increases were not as marked.

Absenteeism.—As in case studies 1 and 2, the measure of absenteeism indicates only relative work attendance during the periods surveyed, and not an actual measure of time lost. The available data indicate, however, that immediately after the shortening of the workweek and the introduction of piecework, absenteeism was cut to half. After several months at the shorter schedule, but with higher earnings, absenteeism increased steadily and finally stabilized at a level somewhat higher than the one which had prevailed during the 6-day week. The explanation advanced by management has been stated in case study 2.

4: *Workweek of 58 hours, day shift, with no wage incentives* vs. *one of 55 hours, with individual wage incentives; squeezer-mold operations in a nonferrous metal foundry; men.*

This is the last group of men studied in the foundry described in case study 1. The 35 studied were on the day shift and belonged to the same squeezer department discussed in case study 3, which was concerned with night-shift workers.

Although these men shifted to a wage-incentive system, their working hours remained nearly unchanged. The change was from 58 hours per week to 55, and was accomplished by shortening Saturday from 8 hours to 5.

FINDINGS OF STUDY

Efficiency.—The introduction of the wage incentive, but with the longer workweek essentially maintained, resulted in a slight increase in efficiency and a small increase in total output. Average hourly output rose by about 6 percent and total output by nearly 3 percent.

Because the reduction in weekly hours had been slight, this change appears to be attributable primarily to the introduction of the wage incentive.

Absenteeism.—With the introduction of piecework, the rate of absenteeism increased from 4.8 percent at 58 hours to 6 percent at 55 hours.

5: *Prewar workweek of 52 hours* vs. *war workweeks of 58 and 52 hours, day shift, individual wage incentives; hot and heavy, man-paced upset-forge operations; men.*

The shop produced axles, shafts, gear blanks, small forgings, and during the war, shells. The operation consisted of heating one end of a steel bar and forging it by means of dies. The hot steel was virtually squeezed into shape by the horizontal motion of one half of the die, set in the forge, against the stationary half of the die. The heater kept the heating oven loaded while the hooker held the bar and the operator guided and turned the bar in the several slots of dies set in the forge. The process was completed by sawing off the forging from the bar, striking a stencil number on it, and putting it into a bin.

Working conditions.—Completed forgings weighed up to 250 pounds. The bar stock, 10 to 18 feet long, from which the forgings were made, was, of course, much heavier. The furnace, the forge, and the bins of finished forgings formed a semicircle, and together they radiated a great deal of heat. Temperatures frequently exceeded 100 degrees and reached 120 degrees in the summer. There was considerable dust and smoke, and the constant hazard from flying sparks. Lighting was fair, and there was adequate work space for the operations involved. Washing facilities were excellent.

Waiting time (i. e., heating cold bars or reheating hot bars until they were nearly white in color) between heats was considerable and ranged from 10 to 25 minutes. When not busy changing dies, the men used the waiting time to rest or to eat. There was no set lunch period. The average amount of waiting time in a 10-hour day came to about 1½ hours.

The work force.—The selected group of operating crews on the day shift represented 48 men. The shift did not rotate. The average crew was composed of operator, heater, hooker, and helper. Turn-over was small, as most workers were old-timers in the company, and wage rates and earnings were relatively high.

Wage incentives.—The forge crews were on a piecework system with a guaranteed hourly minimum rate. Set-up and down-time was paid for at rates 5 and 10 cents less per hour respectively than the base rate.

The plant's safety record was very good. The wearing of goggles and safety shoes was compulsory. First-aid room facilties included special equipment to treat eye injuries caused by flying sparks, excessive light, steel particles, and dust.

Hourly schedules.—Up to December 1941, the nominal workweek consisted of 52 hours, with 5 days at 9 hours and Saturday at 7. With the beginning of the war, the workweek was increased to 58 hours by raising daily hours to 10 and Saturday hours to 8. In September 1942, the department returned to the 52-hour schedule worked before the war.

FINDINGS OF STUDY

Efficiency.—When weekly hours were raised from 52 to 58 at the beginning of the war, a period of 5 months elapsed before performance stabilized under the longer hours. During the early months of the war, efficiencies actually rose above the prewar level, even though weekly hours had been lengthened. After the transitional period, efficiency leveled off at a point 3 percent below that of the former 52-hour week, while absenteeism dropped 0.5 percent below the 52-hour rate of 3.3 percent. The percentage of unproductive time, however, increased markedly under the longer hours, rising from 22 percent at 52 hours to 27 percent at 58. As a result, total output during the 58-hour week increased by only 3.7 percent above that for the 52-hour schedule. When it became apparent that over-all production during the 58-hour week was only slightly above that formerly obtained during the 52-hour week, management reverted to the earlier schedule.

After this cut-back, efficiency increased steadily for 5 months, to the end of the period surveyed. It was higher at this point than during any other month of the entire period covered. It was not possible to tell from the data whether this point represented the level at which efficiency would stabilize during the 52-hour war week, and it is possible that the level ultimately reached may have been higher.

Output.—In any case, output during the 52-hour war week was as high as it had been during the 58-hour war week. The addition of 6 hours had not helped to increase output. In fact, the data suggested that the total output during the 58-hour schedule, if continued for any length of time, might have been only 95 percent of that obtained during the shorter workweek.

The data also indicated that the output level of the 52-hour war week was about 8 percent higher than that of the 52-hour prewar week. At the same time, however, the proportion of unproductive time remained at about the same level (25 percent) as that which had prevailed during the 58-hour week (27 percent). Although the men worked harder, they had to take just about as much time out from actual production.

Absenteeism.—Absenteeism was not an important problem when hours were increased. It exceeded 2.5 percent in only 3 out of the 9 months during which the longer schedule was in effect. During the subsequent 52-hour week, however, the absenteeism loss never fell below 4.2 percent and went as high as 7.8 percent. The posting of absences had only a temporary effect. A visiting nurse, who investigated absences of more than 2 days, found that workers frequently were "just resting." Frequently, however, she found it possible to persuade the men to return to work by appealing to their patriotism.

These facts—the high unproductive time and the higher absenteeism rate—during the final 52-hour week strongly suggest that the effects of fatigue made themselves felt at this time. It should be added also that there was no indication that the 52-hour week was the optimum workweek, and that a shorter schedule might not have proved as productive. It shows only that, in this operation, a 52-hour schedule was as good as a 58-hour schedule.

Work injuries.—There was no appreciable difference in the work-injury experience under the various levels of hours. The plant had an excellent safety program and a consistently good safety record.

Daily output pattern.—The effect of increasing daily hours from 9 to 10 and Saturday hours from 7 to 8 was to eliminate the midweek spurt of output which had been characteristic of the shorter week prior to the war. During the shorter schedule, output rose from Monday through Wednesday, the peak day. The output levels for Thursday and Friday were somewhat lower, but on a par with that of Monday. Saturday's level was higher, probably because it was a shorter day.

During the longer workweek, this peak disappeared. The output level throughout the week remained fairly constant—at the Monday level. In addition, there was a sharp drop on Saturday—the output level was nearly 25 percent lower than for the Saturday under the shorter workweek, probably reflecting accumulated fatigue.

6: Prewar workweek of 50 hours vs. *war workweeks of 58 and 50 hours, night shift, individual wage incentives; hot and heavy, man-paced upset-forge operations; men.*

The men selected for this study worked on the nonrotating night shift of the same department described in the preceding case study. This survey will present only those points in which the night-shift workers differed from the day-shift workers.

The performance of four crews, accounting for a total of 16 men, was traced through the 21-month period studied, from June 1941 through February 1943. Changes in the weekly schedules coincided with those of the day shift. The prewar schedule was 50 hours per week (5 days at 10 hours). By the introduction of Saturday work, usually of 8 hours, the weekly schedule was raised to 58 during the early part of the war. When the day-shift hours were reduced to 52 per week, those of the night shift were put back to 50.

INDINGS OF STUDY

Efficiency.—When hours were reduced from 58 to 50 a week, efficiency increased by 5 percent. The efficiency trend of the night shift generally followed that of the day shift, except that it reached very much higher levels. This trend may be due to the fact that nights are cooler and that fewer forges were operated at night, thus creating less heat in the shop.

As in the case of the day shift, the efficiency of the night shift increased up to 6 percent upon our entry into the war, in spite of the addition of the extra day. After 5 months at longer hours, however, efficiency dropped to about the level maintained during the prewar schedule of 50 hours. When hours were cut back to 50 a week, efficiency rose steadily up to 17 percent above the prewar level for the same schedule, then dropped back to 5 percent. The average efficiency level during the wartime week of 50 hours can fairly be set at about 8 percent above the level for the same hours before he war, and at about 5 percent above the average performance level for productive hours during the 58-hour week.

The percentage of productive time was slightly lower during the 50-hour week than during the 58-hour week, and in general, was lower than that of he day shift. Stated conversely, there was more unproductive time on the night shift.

Output.—When the 8-hour Saturday was added to the workweek, the average increase in output was directly proportional to that of weekly hours. When the workweek was reduced to 50 hours by the elimination of Saturday work, an increase in efficiency and a slight reduction in unproductive time esulted in keeping the volume of output at the same level as under the longer hours. In other words, the 50-hour week was as productive as the 58-hour week.

Absenteeism.—The prewar schedule of 50 hours per week had the lowest ate of absenteeism, 2.3 percent.

When Saturday work was added, the absenteeism loss increased to 4.7 percent of scheduled man-hours. The war period of 50 hours resulted in a slight drop in the absence rate to 4.2 percent—which was still above the prewar rate for the same weekly schedule.

Daily output pattern.—The effect of extending the workweek by the addition of 8 hours on Saturday was to eliminate the midweek spurt of daily output which resulted in a peak on Thursday. As in the case of the shorter workweek, the output level remained lowest on Monday—but at a much lower level. This was followed by a rise on Tuesday; but after that, nearly every day was at a lower output level than the one preceding it. Production on Satday was about as low as on Monday. In general, the average output level for the 58-hour week was considerably lower than that for the 50-hour week on every day of the week from Monday through Friday.

Absenteeism—Injuries.—The comments made in case study 5 on absenteeism and work injuries apply to this group of workers as well.

7: Workweek of 40 hours vs. *workweeks of 50 and 58 hours, individual wage incentives; medium-heavy, machine-paced operations; men.*

The operations studied consisted almost entirely of machining processes, such as those on lathe, shaping, drilling, grinding, and polishing machines, for the production of gear couplings. The work may be characterized essentially as medium, machine-paced operations, affording some rest to the operators on most of the processes. The materials handled varied in weight from 5 pounds to 1 ton, but averaged about 25 to 50 pounds.

Working conditions.—Working conditions may be characterized as fairly good. Ventilation and lighting were good. There were no fumes or dust, no congestion, and the department was quite clean, except for some cutting oil and shavings on the floors. There were no organized rest periods.

The work force.—A control group of about 39 productive workers on day and night shifts, who had been in the department for at least 2½ to 3 years prior to the end point of the survey, were studied. Findings were also obtained for all productive workers in the department. The number of these ranged from 38 to 62, averaging about 50.

Wage incentives.—The department operated on an individual incentive system, which consisted of a guaranteed hourly wage plus a premium based on production in excess of standard.

FINDINGS OF STUDY

Findings cover three distinct hourly levels. From March 1939, through February 1941, the workweek consisted of 5 days at 8 hours, or 40 hours. The following period, March to December 1941, comprised a 50-hour workweek of 5 days at 10 hours. At the beginning of the war an 8-hour Saturday was added for a workweek of 58 hours. This schedule was surveyed for the period January 1942 to March 1943.

Efficiency.—When hours were raised from 40 to 50 a week, efficiency declined by 4 percent, after a lag of 3 months during which efficiency level of the shorter workweek was fairly well maintained.

When an 8-hour Saturday was added at the beginning of the war, the level of efficiency rose somewhat at first, apparently as a result of war morale. But after 6 months at the new schedule, efficiency decreased to a level about 6 percent below that of the original 40-hour workweek. This it will be noted, was only 2 percent below that of the 50-hour week.

Efficiency of the night shift was consistently about 5 percent below that of the day shift and reacted more quickly to changes in hours, but in the same direction.

The efficiency level of the uncontrolled group was consistently below that of the control group, but the experiences of the 2 groups were parallel at the different hourly schedules. This uncontrolled group represented a less experienced group of workers.

It must be remembered that these operations were essentially machine-paced, and that operators could not speed up or slow down operations except for the short period of time necessary to put new work on the machines and remove processed work from the machines. Consequently output varied fairly closely with the number of hours worked.

Daily Efficiency Pattern

During the 5-day week and 8-hour day, efficiency on the day shift built up almost steadily from Monday to a peak on Thursday, with a slight drop on Friday. The effect of the addition of two daily hours was to level out the daily pattern, so that, except for a slight rise on Tuesday, one day was as good as another, but each day's level was lower than that under the 40-hour schedule. When Saturday work was added, the pattern was similar to that of the 50-hour week, but the entire level was still lower.

For the night shift, the 40-hour week pattern of efficiency showed a spurt on Thursday, but this was preceded by a drop from Monday through Wednesday. Friday showed a slight falling off from the Thursday peak. During the 50-hour week, there was a sharp drop on Wednesday with a generally stable level for the other days of the week, all daily averages being below those of the previous schedule. When Saturday was added to the workweek, the pattern was one of a steady downward trend from Monday through Friday, with a slight spurt on Thursday. There was a somewhat higher level on Saturday, which was an 8-hour day.

Absenteeism.—During the 40-hour workweek the average time lost through absenteeism was 2.7 percent.

When the workweek was lengthened to 50 hours, absenteeism, after a period of 3 months reflecting the transition from one schedule to the other, reached an average level of 7 percent.

During the 58-hour workweek, the stabilized level of absenteeism was held to about 4.5 percent, owing to the efforts of a labor-management committee. The data indicate that in the absence of this effort, a level of 10 percent or more might have prevailed.

During the 40-hour workweek, the rates of absenteeism for both shifts were about the same (nearly 3 percent). When hours were lengthened to 50, the average for the day shift rose to 5.5 percent, and for the night shift to 11 percent. During the 58-hour schedule, the rates were 4.4 percent for the day shift and 4.9 percent for the night shift.

The uncontrolled group's rate of absenteeism rose from 5.4 to 7 percent when hours were changed from 40 to 50. It increased to 8.1 percent under the 58-hour schedule. The efforts of the labor-management committee were not nearly as effective with this group as with the older workers.

Daily Absenteeism Pattern

During the 40-hour week, absenteeism for the day shift was highest on Wednesday and Thursday. On the whole, it was higher during the latter half of the week. When daily hours were changed from 8 to 10, the peak of absenteeism shifted to Monday, with successive declines on Tuesday and Wednesday, followed by a stabilized level the rest of the week. The pattern reflects the desire for a longer weekend. During the 58-hour workweek, there was a fairly steady decline in absenteeism from Monday through Friday, and a sharp increase on Saturday. Saturday absenteeism represented nearly half of the time lost during the week.

For the night shift, absenteeism during the 40-hour schedule was highest on the first day, which in this case was Sunday night. Except for Thursday, the remaining days were nearly free of absenteeism. When daily hours were lengthened from 8 to 10, the first day had the lowest rate of absenteeism, with a slight rise on the second day, and a very sharp rise the third day, followed by a stabilized level at this high rate. During the 58-hour schedule, absenteeism was low the first 5 days of the week, with a moderate peak on Saturday. In this case, Saturday work was actually performed Friday night, giving the workers all of the next day to attend to personal affairs. Consequently the rate was not nearly as high as for day-shift workers.

Output.—For the men in the control group, the 25-percent increase in weekly hours from 40 to 50 brought about an increase of 23.5 percent in output. The failure of output to rise by the same percentages as did hours was due to the slight decrease in efficiency and the rise in absenteeism. The rate of increase in output kept pace with that of hours primarily because workers had relatively little control over the speed of operations and because unproductive time (getting ready, cleaning up, etc.) was spread over a longer workday, permitting a proportionately higher utilization of the time for actual machine operations. In terms of hours, 1.9 output hours were gained for each 2 hours added to the schedule.

The 45-percent increase in hours from 40 to 58 per week was matched by an increase of 36 percent in output, a gain of little more than 1½ hours for each 2 hours added to the schedule.

For the newer group of workers, the 25-percent increase in the schedule from 40 to 50 hours brought about a rise of 18 percent in output, or less than 1½ output hours for each additional 2 hours scheduled. The 45-percent increase in hours from 40 to 58 resulted in a 30-percent increase in output, or 1⅓ output hours for each 2 hours added to the schedule.

8: *Workweeks of 40 hours* vs. *48 (6 days)* vs. *48 (5 days)* vs. *55 (6 days), individual wage incentives; medium-heavy, mostly operator-paced machining operations on small gasoline engines; ceilings on earnings; men.*

The majority of operations included such metalworking processes as cutting, drilling, boring, grinding, and polishing. The plant produced gasoline engines ranging from 3 to 9 horsepower.

Operations were well-planned and efficiently organized. Work appeared to be done at a fast pace with little evidence of idle time. The weight of parts manually handled ranged up to 75 pounds and averaged between 25 and 50 pounds. The pace of production was controlled by the operator on the majority of operations. Work was medium-heavy.

Working conditions.—Plant conditions were fairly good. The limit of space-utilization seemed to have been reached without crowding. Lighting was only fair, noise was considerable, especially around a few machines. Washroom facilities were inadequate. There was no plant cafeteria. The first-aid room was well-equipped.

The work force.—During the period selected for study, from October 1940 to September 1942, the work force increased from 261 to 700 men. All of these operators, however, were selected for skill and experience, and consequently the data used cover the entire plant. Subsequent to the period covered by this survey, the labor market had tightened sufficiently to induce management to resort to less experienced operators.

It was not possible to obtain data separately for the day and night shifts. Shifts were not rotated. The day shift started at 7 a.m. and was allowed a half hour for lunch. The night shift began at 5 p.m. with no time out for lunch. The men ate when they wanted to eat.

Wage incentives.—Contrary to a frequently found practice, the night shift received no shift bonus. Pay for Saturday was at time and a half, for occasional Sunday work at double time, even though weekly hours for the first 5 days of the week might have totaled less than 40. This policy was adopted to make work over the weekend more attractive. All work was done under a piece-rate system.

As a form of rest period, workers were allowed a specified 5-minute period, both morning and afternoon, to buy refreshments from a lunch cart.

Hourly schedules.—The survey covers the 24-month period from October 1940 through September 1942. Thereafter shortages of materials and a dilution of the average skill of the work force precluded any valid conclusions based on changes in hours.

During the 2-year period, hours went from 40 to 48, from 5 days at 8 hours to 6 days at 8 hours. Then operations dropped to 5 days a week, but with 9½ hours per day for a weekly total of 47½ hours. Finally, a sixth day at 8 hours was added for a weekly schedule of 55½ hours.

FINDINGS OF STUDY

Efficiency and output.—Average hourly output was as good at each of the schedules of longer hours as during the 40-hour week, output increasing in direct proportion to the increase in hours. Thus, the output rate was about equally good at 40, 48, 47½, and at 55½ hours a week.

These findings, however, are subject to the important qualification that output at 40 hours undoubtedly would have been better had the workers not feared to earn more than $1 per hour. When, later, management lifted the hourly base rates above $1, and repeatedly assured the men that rates would not be cut, the men really tried to earn all they could.

The facts obtained, therefore, merely prove that workers can work as efficiently at 55½ hours a week as they did at 40—provided they did not extend themselves fully at the shorter schedule because of a managerial policy of limiting hourly earnings.

Absenteeism.—Time lost because of absenteeism was three times as high during the 55½-hour week as it was during the 40-hour week. The respective rates were 5.8 percent and 1.8 percent.

At 55½ hours absenteeism losses rose up to 10 and 11 percent during the summer months. During the 6-day week, absenteeism was highest on Saturday. More time was also taken off around holidays as evidenced by a December rate of absenteeism of 11.9 percent during the 55½-hour, 6-day week, as against one of 2.3 percent for the same month under the 40-hour, 5-day week.

During the 5-day week, the absenteeism loss was fairly well distributed throughout the workweek. When a sixth day was added, absenteeism was marked on Saturday. Furthermore, it was considerably higher for the 55½-hour week than for the 48-hour week, both consisting of 6 work days.

Injuries.—Work injuries were considerably more frequent as weekly hours increased beyond 40. The average rate of 44 injuries per 100 workers per month during the 40-hour week involved almost entirely first-aid cases only. At 48 hours, there were 76 such injuries per 100 workers per month. With the dropping of the sixth day for a 47½-hour week, the rate decreased to nearly 70, but increased again slightly to 71 under the 55½-hour, 6-day week. In the experience of this plant, the workweeks of 55½, 48, and 47½ hours were about equally hazardous—but each level was decidedly more hazardous than the 40-hour week.

9: Workweek of 45 hours vs. *one of 58 hours, group wage incentives; fairly hot and heavy, operator-paced welding operations; men.*

The work consisted of assembling, clamping into place, and welding large metal parts, many of them used on battleships. The process usually involved climbing up and around the framework and required considerable agility. All of the work was operator-paced. It was fairly hot and heavy. Because of the danger of flying sparks, welders were required to wear heavy protective clothing even during hot summer weather.

Working conditions.—Conditions were good, considering the type of work performed. As the shop was completely open on one side and well-ventilated.

there was little danger of discomfort from welding fumes. There was plenty of room. Although there were no organized rest periods, workers took time out when they thought it desirable. Smoking was permitted in the shop. The men carried their lunches and ate in the shop during the half-hour lunch period. Although the first-aid room was well-equipped, workers in this shop usually did not bother to report there and saved time by receiving first-aid treatments from the foreman.

Wage incentives.—The welders worked on a premium wage-incentive system under which each man was paid as premium his proportionate share of the hours saved from the established time standards, many of which stretched over days and weeks until the specific piece of work had been completed. The welders were paid on a straight hourly basis. Premium was paid when a task was completed. Time standards had remained unchanged during the few years preceding the survey period, so that the performance of the 275 welders in this shop was a good indication of their efficiencies under various patterns of daily and weekly hours.

In addition to time-and-a-half pay for all overtime, a 2½ to 5 percent bonus was issued every 3 months based on the over-all plant output. The bonus was paid on each man's total earnings, including overtime and premium pay. A shift bonus of 7 cents per hour was paid to the second shift and 11 cents to the third shift.

Hourly schedules and shifts.—Shifts were rotated every 3 weeks. Workers, however, often interchanged shifts to suit themselves. Prior to November 1942, the welding shop was on a 45-hour schedule, with 6 days of 7½ hours each. The shop worked around the clock, having three shifts. When male welders became scarce, the shop went to two shifts, working 5 days at 10 hours and Saturday at 8 hours for a weekly total of 58 hours.

FINDINGS OF STUDY

Efficiency.—During the 45-hour week, the welders produced on the average 21 percent above what the standard called for. The same rate of efficiency was maintained when weekly hours were increased to 58.

Absenteeism.—Department-wide absence data were not available. A check of the percentage of scheduled time lost due to absenteeism among 70 individual welders revealed that an average of 4.2 percent of working days were ost during the 45-hour week and 6.9 percent during the 58-hour week. This ncrease resulted from the lengthening of daily hours, as 6 days per week were worked during both schedules.

During the longer workweek, absences because of alleged illness more than doubled—the rate was 0.7 percent during the 45-hour week and 3.1 percent at 58. The absence rate for "personal reasons" was 2.7 percent at 45 hours per week and 3.6 percent at 58. Time lost because of work injuries was 0.7 percent at 45 hours and about the same at 58 hours. If the losses from injures and illness are combined, the comparative rates for short and long hours are 1.4 and 3.1 percent, respectively.

Output.—The increase in output lagged only about 3 percent behind the increase in hours, due almost entirely to the higher absenteeism loss at 58 hours. The workers were 97 percent as effective per hour during the 58-hour weeks as they formerly had been at the 45-hour week.

10: Comparisons of efficiencies by shift and by sex of workers; light, operator-paced, and automatic-machine operations at hourly schedules varying between 45 and 66 hours per week; indirect wage incentives.

This plant was engaged in the processing of a large variety of metal parts for war purposes, most of them small and light. About 70 percent of the workers were women. All employees were paid at hourly rates. Individual efficiency records were kept, however, to serve as bases for promotions. Fairly 'tight" time-study production standards were used to measure efficiencies. Erratic working schedules and insufficient absence records limited the study to comparisons of efficiencies of men and women by shifts in several departments.

Working condition.—Floors were kept clean and equipment was modern and well-maintained. Washroom facilities and lockers were insufficient in number because of lack of space, were poorly lighted, and not very clean. The size of the cafeteria was entirely inadequate for the 9,500 workers of this plant. Lighting and ventilation were fairly good.

Hourly schedules and shifts.—Women generally worked 45 hours a week, 6 days at 7½ hours each, on three nonrotating shifts. Hours for men varied greatly, as indicated in the selected departments. Most departments had a half-hour lunch period, frequently paid for by the company. Women usually were allowed 15 minutes and men 10 minutes for rest in the middle of each half of the workday. Working schedules were staggered and 22 different starting times during the day were used to ease problems of transportation. The survey extended from the middle of 1942 to the middle of 1943.

A 10-percent premium was paid to both of the second and third shifts.

Turn-over.—According to company officials, turn-over rates of 30 to 40 percent were not uncommon, and occasionally levels of 60 to 70 percent were reached in individual departments. Many of the women workers were new to plant operations and apparently did not like them, and many others found better pay elsewhere.

Although most of the turn-over was due to "quits," a considerable number of the separations were regarded by the company as "discharges." An absence of 1 week without notice to the company was cause for a "discharge." Obviously, many of the discharges more properly could be labeled as "quits."

Absenteeism.—Absences, although claimed to be frequent, were not followed up. During the time of the survey, no effective method had been found to reduce losses due to absenteeism, or even to halt the upward trend. Because of the nature of plant records and practices, it was not possible to obtain satisfactory measurements of absenteeism.

Safety.—The first-aid room was well-equipped. Trained nurses and physicians were in attendance. Information on injuries was limited to the data compiled by the safety department, which showed a very low frequency rate of 4.3 for 1942. Safety conditions were generally good.

Departments A, B, and C

The three departments were doing similar work on operator-paced, light machine operations. The weight of pieces handled ranged up to 1 pound. Most operations consisted of picking up a part, fitting it into the machine, operating a hand lever or foot pedal, and removing the processed part. Many of these operations moved very quickly and involved the maintenance of a steady work rhythm.

The following statement presents the findings for these departments:

Workweek	Efficiencies, by shift			
	All shifts	First	Second	Third
Department A				
Men: 45–60-hour week	96.5	97.1	....	95.3
Women: 45-hour week	97.9	98.8	98.0	94.0
Department B				
Men: 45-hour week	95.4	96.9	95.1	93.9
Women: 45-hour week	97.8	105.3	95.7	89.2
Department C				
Men: 45-hour week	99.1	99.1	....	....
45–66-hour week	97.6	97.6	....	....
Women: 45-hour week	102.8	100.4	104.6	103.5
60-hour week	104.7	102.9	106.3	105.5

These data may be summarized as follows:

Women were more efficient than men at light machine operations which involve rhythmic and fast handling of light parts.

The first shift was usually the most efficient and the third shift the least efficient for both men and women. The difference in efficiency between the first and third shifts was more marked for women than for men. The data for women workers in department C ran counter to the findings for departments A and B, but the reason for this could not be ascertained. Working conditions and supervision for departments A and C were identical.

At this type of work a 60-hour week and 10-hour day for women was as efficient as the 45-hour week and 8-hour day (included ½ hour for lunch). In fact, the efficiencies at the higher hourly levels were slightly better. This was ascribed by the supervisors to the fact that a steady rhythm was reached after a warming-up period at the beginning of the day, and that this rhythm could be maintained satisfactorily for the remainder of a 10-hour day. In department C, each of the three shifts at the longer hourly schedule had a higher average efficiency than during the shorter schedule.

For men, working up to 11 hours per day, this did not seem to be the case. Data were available only for the 19 men studied on the day shift in department C. Here the efficiency level during the 45- to 66-hour week (97.6) was slightly lower than that for the 45-hour week (99.1).

Department D

This department processed small parts for aircraft engines, such as bolts, studs, nipples, screw bushings, set screws, plugs, nuts, and adaptor bolts. As a high degree of precision was required, emphasis was on accuracy rather than speed. As a consequence, time standards were very liberal. Work consisted mostly of operator-paced machine operations, such as drilling, grinding, tapping, threading, cutting out slots, polishing, burring, counterboring, and countersinking.

Efficiencies for men were recorded for workweeks of 45, 55 to 66, and 60 hours. For the same periods, the weekly schedule for women remained constant at 45 hours. The groups studied consisted of 24 men on the first shift, 14 on the second, and 20 on the third during the 45-hour week. During the longer workweek, consisting first of alternating 5 and 6 days at 11 hours, and later 6 days at 10 hours, only two shifts were operated, with 30 men on the first shift and 28 on the second.

The 29 women were evenly divided among three shifts, with 10 on each of the first and second shifts and 9 on the third.

The findings are as follows:

Workweek	Efficiencies, by shift			
	All shifts	First	Second	Third
Men:				
45-hour week	101.3	101.5	101.2	100.9
55–66-hour week	101.6	101.8	101.3	....
60-hour week	102.3	103.3	100.9	...
Women:				
45-hour week	103.3	103.6	102.9	103.0

At light and simple machine work requiring great accuracy, women were more efficient than men. This was true from the groups as well as for each shift.

For men, efficiency was as high during an 11-hour day as during a 10-hour day, although there was some indication that—for the day shift at least—a 10-hour day was slightly better. The data for the 60-hour week, however, did not cover a long enough period to justify a definite conclusion. As in the case of the three departments already discussed, the work involved a warming-up period and the maintenance of a rhythm. In department D, however, the rhythm was slower because of the greater accuracy required.

There was relatively little difference between the shift averages of men or women during the 45-hour week. The slight differences tended to reenforce the point made in connection with departments A and B, to the effect that the first shift had the highest and the third shift the lowest efficiency level. The fact that there was so little difference probably was due to the nature and tempo of the work.

Department E

In sharp contrast with the work in the preceding four departments, that in department E was entirely machine-paced. All work was done on automatic screw machines. Raw stock bars, up to 500 pounds in weight, were fed into a battery of machines from trolleys. Most of the "first operation machines," performing up to six operations, were run by men. Women did "second operation" work on smaller stock, using screw machines that performed only up to three operations. Work was fully automatic. The operator's task was to keep the machines fed, gauge the finished pieces, adjust the die sets, regulate the flow of the cutting oil, and generally watch the performance of the machines.

Men worked 46 to 69 hours a week, two shifts of 11½ hours each. Off days were staggered so that a man could work from 4 to 6 days a week. Women worked three shifts of 8 hours each. No time was set aside for rest or lunch periods, as considerable idle time was involved during machine operations. The equipment was modern. There was relatively little noise, and lighting was good. Of 28 male operators, 14 were on each of the two shifts. The 39 women operators were almost evenly divided, with 12 on the first shift, 13 on the second, and 14 on the third.

The findings for this department are as follows:

Workweek	Efficiencies, by shift			
	All shifts	First	Second	Third
Men: 46–69-hour week	101.9	100.1	104.2	....
Women: 45-hour week	98.9	96.4	99.6	100.3

The findings for this department were in direct contrast with those of the other departments already discussed.

1. As operators of automatic multiple screw machines, men were more efficient than women. The average efficiency level for all men was 101.9, while that for all women was 98.9. The general finding held for the individual shifts as well.

For men, working 11½ hours a day, the second shift's performance level was superior to that of the first shift. For women, working 8 hours a day, the third shift had the best and the first shift the lowest efficiency level. The second shift's average, however, was not much below that of the third.

Without additional study of similar operations, the relative performance of the various shifts cannot be held to be typical of this kind of work. The possible explanation that seasonal heat during the day might have influenced the lesser performances of the first and second shifts does not hold here because the period surveyed did not cover the summer months.

11: *Workweek of 45 hours* vs. *55 hours for women, day shift, indirect wage incentives; light, operator-paced machining operations.*

Operations consisted of machining processes on lathes, grinders, broachers, and similar metal working equipment involved in the production of bearings and washers for motors and other operating parts of airplanes. The pace followed was quite fast and permitted the operators very little idle time.

Working conditions.—Working conditions were exceptionally good. The department was air-cooled and sound-proofed. Noise was moderate except around the punch presses. There were no fumes or dust. Lighting was excellent. Aisles were well-defined and kept clear. All equipment was well-guarded and well-spaced. There was an intensive safety effort, which included lectures, use of special safety equipment, and constant inspection by safety engineers. The success of this program was reflected in the fact that injuries as measured by the standard injury frequency rate did not rise when the workweek was lengthened from 45 to 55 and 57 hours in the department.

Wage incentives.—There was no wage-incentive system of the usual type in this department. Measures of efficiency were maintained to determine workers' promotions and wage increases. Wage rates were stratified, depending on the average hourly output of the employee.

FINDINGS OF STUDY

The experience of a selected group of 66 women on a day shift was studied.

Efficiency.—When daily hours were increased from 7½ to 9½ hours for 5 days of the week with the retention of a 7½-hour Saturday, efficiency showed no change.

Absenteeism.—Absenteeism rose from 3.3 to 4.5 percent when the workday was lengthened. In any case, the rates in either period were not excessive. Company officials attributed this to an intensive campaign to keep absenteeism down.

Output.—Output rose 20.9 percent as a result of the 22.2 percent increase in hours with a stable level of efficiency and a slight increase in absenteeism. Thus, the change from a 7½- to 9½-hour schedule for 5 of the 6 work days had the effect of furnishing almost 1.9 additional output hours for each 2 hours added to the schedule.

12: *Workweek of 45 hours* vs. *57 hours for women, evening (second) shift, indirect wage incentives; light, operator-paced machining operations.*

Operations and working conditions, except for the working hours of the day, for this group are similar to those in case study 11, as these women were in the same department.

FINDINGS OF STUDY

Findings are for a selected group of 61 women who experienced a change in scheduled hours from 45 to 57 per week by the addition of 2 hours to the original 7½ hours for 6 days of the week.

Efficiency.—The change from the 7½- to the 9½-hour day resulted in a decrease of 7 percent in efficiency for women on this shift.

Absenteeism was 2.7 percent during the shorter workweek. The rate rose to 4.8 percent when the hours were lengthened.

Output increased by 15.3 percent with the increase of 26.7 percent in the workweek. The disparity resulted from the drop in efficiency and higher absenteeism during the longer schedule. As a result, for every 2 hours added to the schedule, only about 1 hour's additional output was obtained.

13: Workweek of 45 hours vs. *one of 55 hours for women who changed from an evening (second) to a day shift, indirect wage incentives; light, operator-paced, machining operations.*

These women were in the same department as those in case study 11. Operations and working conditions were identical. These workers moved up to the day shift when the workweek was lengthened. The change resulted in the loss of a shift bonus of 5 cents an hour, and a new orientation to transportation requirements, home duties, eating and sleeping habits, shopping practices, etc.

FINDINGS OF STUDY

The experience of a selected group of 26 women was studied. The change from a 45- to a 55-hour workweek was effected by changing daily hours from 7½ to 9½ for 5 days in the week, with the retention of a 7½-hour Saturday.

Efficiency declined 8 percent during the longer workweek, and with the changed shift.

Absenteeism rose from 2.2 percent to 5.8 percent under the longer schedule.

Output rose only 8.4 percent when the workweek was increased by 22.2 percent. In effect, only about three-fourths of an hour of additional output was achieved for each 2 hours added to the schedule.

14: Workweek of 45 hours vs. *one of 55 hours for women who changed from a night (third) to a day shift, indirect wage incentives; light, operator-paced machining operations.*

These women worked in the same department as those in case study 11. Operations and working conditions were identical, except that the change in shift meant for these workers the loss of a shift bonus of 10 cents an hour, and the necessity of acclimating themselves to new transportation schedules, a revised program of home duties, eating and sleeping habits, etc.

FINDINGS OF STUDY

Findings are based on the experience of a selected group of 22 women who changed from a night shift to a day shift when the workweek was lengthened from 45 to 55 hours. The change in daily hours consisted in the addition of 2 hours to the previous 7½-hour day for 5 days of the week, with the retention of a 7½-hour Saturday.

Efficiency.—The lengthening of the workweek and the change in shift brought about a 7.1 percent decrease in efficiency.

Absenteeism averaged 3.3 percent during the shorter hours. The rate rose to 4.1 percent after the change.

Output rose 12.6 percent when the workweek was lengthened 22.2 percent. Thus a little more than 1 output hour was added for each 2 scheduled hours added.

15: *Workweek of 45 hours* vs. *one of 57 hours for women who changed from a night (third) to an evening (second) shift, indirect wage incentives; light, operator-paced machining operations.*

Operations and working conditions were identical with those in case study 11. These women worked in the same department as those in the previous study. The change in shift meant for these women revisions in transportation facilities, home duty schedules, eating and sleeping habits, etc.

FINDINGS OF STUDY

The findings are for a selected group of 59 women who experienced a simultaneous change in working hours and work schedules. The workweek was lengthened from one of 6 days at 7½ hours, or 45 hours a week, to one of 6 days at 9½ hours, or 57 hours a week.

Efficiency.—The change in shift and the increased hours brought about a decline of 3.4 percent in efficiency.

Absenteeism before the change averaged 3 percent. The rate under the longer hours rose to 4.7 percent.

Output rose 20.1 percent during the second period when the workweek was extended by 26.7 percent. Thus, a little better than 1½ hours of output were added for each 2 hours added to the schedule.

16: *Workweek of 45 hours* vs. *one of 55 hours, day shift; indirect wage incentives; light, operator-paced machining operations; men and women.*

The plant studied was engaged in the production of metal bearings. It belonged to the same company involved in case studies 11 to 15, but was located in an older, less modern building. Operations consisted almost entirely of machining processes on lathes, drill presses, grinders, millers, broachers, and similar metalworking equipment. The weights handled varied from 1 to 70 pounds, the heavier parts being lifted by hand cranes. Women worked on the lighter materials. The work may be characterized as light, operator-paced machining operations.

Working conditions.—Working conditions were good. Ventilation and lighting were adequate, and noise was moderate, although there was no air-conditioning or sound-proofing. There were no fumes or smoke. Aisles were defined and kept clear. There were no organized rest periods.

Wage incentives.—Wage rates were based on a detailed placement and advancement program. There was no wage-incentive system of the usual type. Efficiency measures were maintained as a basis for workers' promotions and wage increases. The method used was the same as described in case study 11.

FINDINGS OF STUDY

Findings are for all workers on the shift. During the period surveyed there were about 100 workers in the group. About 75 percent were men and the remainder, women.

Efficiency.—Efficiency declined by 3.6 percent when hours were lengthened from 45 to 55 per week. (This was accomplished by increasing daily hours from 7½ to 9½, but retaining 7½ hours on Saturday.) The pattern of daily efficiency shows that the fourth day, Thursday, was the best day during the period of the short workday. There was a considerably lower level of efficiency on Friday, with some improvement on the sixth day. During the 9½-hour day, the level of efficiency was lower for each day than in the preceding period. Except for a slight drop on Tuesday, there was little difference between the levels for the first 4 days. Again, there was a drop on the fifth day, with a slight improvement on the sixth, this last being related perhaps to the fact that only 7½ hours were worked on that day.

Absenteeism.—Absenteeism rose when the workweek was lengthened. The rate was 1.7 percent during the shorter workweek and 3.6 percent under the longer schedule. In both periods, the rate was not excessive. Under the shorter hours, absenteeism was highest on the first workday of the week, dropping successively to a low on Friday, with a fairly sharp rise on Saturday. The lengthening of 5 of the workdays by 2 hours each raised the level of absenteeism for each day but did not cause any significant change in the relation of the daily levels, except to raise the Saturday level to the highest of the week, slightly above that of Monday.

Output.—Output showed a 15.9 percent rise when the workweek was lengthened by 22.2 percent. In other words, slightly less than 1¾ hours of output were gained for each 2 hours added to the schedule.

17: *Workweek of 45 hours* vs. *one of 57 hours, night shift, indirect wage incentives; light, operator-paced machining operations; men and women.*

This study covers the experience of all workers on the night shift in the same department and on the same operations as those in case study 16. During the period studied there were about 50 workers in this group, approximately 75 percent of whom were men. During the period of the shorter workweek these workers were divided into an afternoon and a night shift. When hours were lengthened the two shifts were combined into one night shift.

Working conditions were similar for both groups.

FINDINGS OF STUDY

Efficiency.—Efficiency dropped 6.7 percent when the workweek was lengthened from 45 to 57 hours by increasing daily hours from 7½ to 9½. Daily efficiency patterns indicate that during the period of the 7½-hour day, the third day, Wednesday, was the peak day, but was closely matched by Friday. During the longer workweek, the week began on Sunday night. During this period the midweek peak was lost and the levels for the first three days, Sunday through Tuesday were constant. The level for Wednesday was lower, with levels for Thursday and Friday still lower.

Absenteeism.—Absenteeism rose from a level of 3.6 percent during the 45-hour workweek to 6.1 percent during the 57-hour workweek. Under the shorter schedule, daily absenteeism was low during the first 4 days of the week, the lowest point being reached on the fourth day, Thursday. Friday showed a much higher rate, and Saturday had the highest daily level of the week. During the longer hours the pattern showed a sharp peak on Sunday, the first workday, a marked drop on Monday, a lower but fairly even level for Tuesday through Thursday, and a very sharp rise on Friday.

Output.—Output rose by 14.8 percent with the 26.7 percent increased in the schedule, a gain of about 1 hour of output for each 2 scheduled hours added to the week.

18: Workweek of 58 hours vs. *one of 48 hours, group wage incentives; medium-heavy, operator-paced machining and assembling operations; men and women.*

The operations consisted of processing steel sheets, which weighed about 90 pounds initially, into airfield landing mats. The processes used were evenly divided between machining and hand operations. The steel sheets, about 2½ feet wide and 10 feet long, were trimmed to size, embossed, holes were punched, bayonet fasteners and slots for interlocking the mats were punched and interlocked, and the resulting mats—now weighing about 65 pounds—were degreased, painted, baked, bundled, and loaded into freight cars.

The mats were moved along the production lines by means of conveyors or overhead tracks. In terms of physical exertion, the work was medium. The speeds of individual operations were entirely within the control of the operators.

Working conditions.—On the whole, working conditions were good. Illumination and ventilation were adequate. Except for the immediate vicinity of the spray-painting booths, the air was clean. Housekeeping was good and there was little congestion or crowding.

There were no showers and no eating facilities of any kind—not even a place to eat.

During the 8-hour day, there were no organized rest periods. Estimates of time voluntarily taken out from work at the production lines, with utility men stepping in as replacements, ranged between 20 and 30 minutes per day. During the 10-hour day, a rest period was called at the end of 8 hours.

The work force.—During the first period surveyed (the 58-hour week), the number of workers studied numbered 80. Only one shift was operated. During the second period (the 48-hour week), the number of workers had grown to 140, and two shifts were used. None of these operators had any prior experience in the production of landing mats, and most of them were new to the plant. Only about half of them had some industrial experience before coming into this department.

The work force during the 58-hour week period surveyed—May through August 1943—consisted entirely of men. During the 48-hour period—January through April 1944—about 15 percent were colored women, selected for size and strength. In view of the kind of operations performed, it is believed that the change in the size and composition of the group should not have influenced the results of the survey.

Wage incentives.—A bonus was paid for all production in excess of a fixed quota, and averaged about 25 percent of the base pay. A penalty was assessed for spoilage above a set limit. Average hourly earnings came to about $1.10.

FINDINGS OF STUDY

Efficiency.—When daily hours were decreased from 10 to 8 for 5 days of the week, with the retention of the 8-hour Saturday, hourly efficiency increased by 15 percent.

Absenteeism.—Absenteeism remained at about the same high level during each of the two periods—10.7 percent during the 10-hour day schedule and 10.4 percent during the 8-hour day schedule. (It should be noted that 6 days were worked under either schedule, so that Saturday absenteeism was a problem in each case.)

Output.—The net effect of the decrease in daily hours from 10 to 8 was a lowering of the total output level by about 8 percent. Against this, the decrease in scheduled hours amounted to 17 percent. Consequently, 1 hour's output was lost for each 2 hours dropped from the schedule. Stating this finding in reverse, the plant had gained only 1 hour's output for every 2 hours worked above 48 per week. Half of the added hours were wasted.

Injuries.—Furthermore, work injuries were about three times as frequent during the longer hours. Although most injuries consisted of minor cuts and bruises, the department averaged 208 such injuries per 100 workers during the 48-hour week, as against 680 during the 58-hour week.

The time lost because of disabling injuries showed much the same picture: For each 100 workers, 23 days were lost during the shorter work schedule, as against 128 during the longer schedule.

19: The effectiveness of Sunday work for workers on light, operator-paced machining operations; individual wage incentives; men.

The plant studied manufactured drills and reamers. Operations consisted of cutting steel rods to proper lengths and grinding, fluting, and tempering these lengths into drills and reamers. This work may be described as light, operator-paced machining operations.

Working conditions.—Working conditions were good. Light was adequate as was ventilation. There were no fumes, and noise was moderate. Aisles were narrow but were kept unobstructed.

Wage incentives.—The wage incentive system consisted of a bonus based on each worker's individual efficiency, with fixed increases for specified percentages above the production standard. There was a ceiling of 30 percent above base pay beyond which the workers were not paid for additional output.

Safety.—A safety program was carried out by a labor-management safety committee.

Hourly schedules.—The performances of a selected group of 30 male operators on three shifts were studied under 4 different levels of scheduled hours. These schedules were: (1) A straight 56-hour workweek of 7 days of 8 hours each; (2) 2 weeks of 56 hours, and one of 48, or every third Sunday off; (3) alternating weeks of 56 and 48 hours, or every second Sunday off; and (4) a straight 48-hour workweek of 6 days of 8 hours each.

FINDINGS OF STUDY

Efficiency.—Efficiency increased 17 percent when the schedule was changed from a straight 7-day week to one with every third Sunday off. It rose another 11 percent when the men worked only every other Sunday. It rose only 1 percent more when Sunday work was eliminated entirely. It is believed, however, that it would have risen still further—by about 6 to 8 percent—had it not been for the 30 percent ceiling on bonus. This ultimate level would be one-third again as high as it was under the 7-day workweek. In any case, the 6-day schedule is clearly indicated as having been the most efficient of those studied.

Absenteeism.—Absenteeism averaged 4.1 percent during the straight 56-hour workweek, and 7.8 percent during the period of 2 weeks at 56 hours and 1 at 48 hours. At this time the company paid an attendance bonus of increasing amounts for every month of perfect attendance during a 3-month period. This bonus was discontinued when the schedule was changed to one of alternating 56- and 48-hour workweeks. During this period the rate of absenteeism was 8.2 percent. When Sunday was eliminated from the workweek entirely, the rate was slightly less—7.3 percent. When Sunday was scheduled, it had the highest daily rate of absenteeism. Next in order came Saturday; and third, Monday. Attendance was best on Friday, which was pay day.

For the plant as a whole, the first shift, with the highest proportion of old-time workers, had the lowest absenteeism rate. It was not much higher on the second shift. The third shift, with about one-fifth of the labor force, and with the lowest proportion of old-time workers, was said to account for 50 percent of the absenteeism. This shift also had the highest proportion of women, whose absenteeism rate was reported to be twice that of men.

Among the reasons advanced by management for the high rates of absenteeism were: (1) The 7-day week was too long; (2) earnings were high and the men had no time to spend their money.

Output.—Output increased 6.8 percent when the average workweek was decreased by eliminating one out of every three Sundays as a work day. It was increased by a total of 13.8 percent when the workweek was further shortened, making only alternating Sundays workdays. During the 48-hour workweek period, output showed a net gain of 6.8 percent. Output was highest during the schedule calling for work every other Sunday. If the assumption as to the true efficiency level in the absence of bonus limitations is sound, however, it appears that the output level during the straight 6-day week would have been equally as high. In effect, this means that the workers were capable of producing as much on a straight 6-day week as during a straight 7-day workweek or under schedules requiring work on every second or third Sunday.

Injuries.—The incidence of work injuries, as expressed in the average number of disabling and nondisabling injuries per 100 workers per month, showed no appreciable variation during the different work schedules, as shown by the following averages:

Work schedule	*Number of injuries*
7-day week	3.6
Every third Sunday off	3.8
Every second Sunday off	3.1
Every Sunday off	3.7

20: *Workweek of 40 hours* vs. *one of 60 hours, day shift, group wage incentives; medium-heavy, operator-paced machining operations; men and women.*

This department produced 105 mm. shells. The work consisted primarily of the operation of metalworking machines such as grinders, millers, lathes, drill presses, and similar equipment. About 14 types of machines performed about 30 operations on the shell. The rough casting, weighing about 30 pounds, passed from machine to machine by means of gravity conveyors. In general, the work may be classified as medium in physical effort required, essentially machining, primarily operator-paced, and affording very little idle time to the operators.

Working conditions.—Working conditions were fairly good. Work areas were adequate in size and unobstructed. Lighting and ventilation were good. Noise, however, was shrill and of considerable volume. Two 10-minute rest pauses were permitted during each shift.

The work force.—During the period studied, approximately 50 men and 15 women were employed on the day shift. Employee morale appeared to be excellent. This was attributed to the immediate and obvious relation of the product to the war effort.

Wage incentives.—A daily and weekly incentive bonus were paid for all shells produced in excess of a fixed departmental quota.

Hourly schedules.—A 40-hour workweek (5 days at 8 hours) was scheduled through May 1943. Responding to the need for increased production, management increased the scheduled workweek to 55 hours (5½ days at 10 hours and finally to 60 hours (6 days at 10 hours). The data permit a comparison of labor performance during the 40- and 60-hour workweeks.

FINDINGS OF STUDY

Efficiency averaged a drop of 22.3 percent during the longer workweek.

Absenteeism losses increased sharply during the longer work schedule. The absenteeism rate rose from an average of 5.7 percent during the 40-hour week to 10.8 percent during the 60-hour schedule.

In terms of total output, the increase of 50 percent in scheduled hours resulted in an increase in output of only 5.5 percent. Thus, given the same hourly efficiency and absence rate which prevailed during the shorter workweek, the additional output gained during the longer workweek could have been obtained by increasing scheduled weekly hours from 40 to about 43.

Injuries (nearly all minor and requiring only first aid) increased in rough proportion to the increase in hours. During the shorter workweek, approximately 109 injuries were sustained by 100 workers per month. The corresponding average rose to 163 during the longer workweek.

Another apparent result of the long work schedule was a sharply increased rate of voluntary quits. During the 40-hour workweek, an average of 3.5 workers voluntarily left the company each month for every 100 workers on the pay roll. The corresponding average during the 60-hour schedule was 7.1. It is impossible to determine to what extent this higher figure reflected experience with different types of workers, and to what extent it was due to longer hours. It is very likely that both of these factors were involved in the sharp increase in the quit rate.

After 7 months at the longer hours, the work schedule was cut back to a 48-hour week, with 6 days at 8 hours each.

21: Workweek of 40 hours vs. *one of 66 hours, night shift, group wage incentives; medium-heavy, operator-paced machining operations; men and women.*

This study deals with the performance of a group of night-shift workers in the plant described in case study 20. The operation, working conditions, and pay incentives were the same for this group as those indicated in the previous case study.

The company employed about 45 men and 10 women on this shift. The workweek was increased from 40 hours, 5 days at 8 hours, to 66 hours, 6 days at 11 hours.

FINDINGS OF STUDY

Efficiency.—A comparison of the levels of efficiency achieved during both schedules reveals that the group was 20.6 percent less efficient during the longer hours.

Absenteeism.—The absence rate rose from 3.7 percent during the 40-hour workweek to 13.3 percent during the longer workweek.

Output.—The composite effect of a 65-percent increase in scheduled hours, reduced efficiency, and higher absenteeism was an increase in output of only 9 percent. In terms of hours, the addition of 26 hours to the workweek resulted in an increase of only 3½ hours of output. The same result could have been achieved by extending the original 40-hour week to 44 hours. The additional 22 hours worked up to the 66-hour level were completely wasted.

After 7 months at the longer hours, the shift was cut back to 6 days at 8 hours each, or 48 hours per week.

22: *Workweek of 48 hours* vs. *one of 55½ hours, no wage incentives; medium-heavy and heavy operator-paced chipping, grinding, and welding operations; men.*

This study was conducted in the finishing department of a small steel casting foundry. The operations consisted of cleaning, grinding, chipping, and welding of castings delivered to this department after having been poured in the molding department. All of the operations were entirely operator-paced. The work ranged from medium-heavy to heavy, depending on the size and weight of the castings (which varied between 20 and several hundred pounds) and afforded the workers very little idle time.

Working conditions.—Foundry work usually is dirty and frequently hot. This foundry conformed to the usual pattern. Illumination in the department was good. Powerful fans removed fumes and smoke and, during the summer, helped in keeping the average temperature from rising above 90°F. Aisles, generally, were clear of obstructions. While there were no organized rest periods, voluntary rest periods consumed from 30 to 45 minutes per day. All work was done at straight hourly rates. There was no wage-incentive system of any kind.

Hourly schedules.—During 1942, the company scheduled a 48-hour workweek, 6 days at 8 hours for the average work force of 80 men in the department. In 1943, the labor force declined to 65 men and weekly hours were raised to 55½, 5 days at 9½ hours and Saturday at 8 hours.

FINDINGS OF STUDY

Efficiency.—A comparison of departmental performance during both levels of hours reveals that efficiency remained essentially unchanged when weekly hours were raised from 48 to 55½. It actually increased slightly by 0.2 percent.

Apparently, the operators were able to maintain the same pace during the 8- and 9-hour days. The finding that the efficiency of men on day work and without any wage incentive remains about the same at levels of long and short hours parallels a similar finding in an earlier study.[3]

In the light of other findings for men working under wage incentives, the conclusion appears warranted that, in this department at least, men on day work—and apparently operating at a slower tempo than if on piecework—can be as efficient during a 9½-hour day and 55½-hour week as they can during an 8-hour day and 48-hour week. In other words, the work pace during the shorter workweek was not so fast as to be impaired when the workday and workweek were lengthened.

It is also likely that the high morale of the workers during 1943—a wartime morale—had an important bearing on the maintenance of an efficiency level which might have dropped had the longer hours been in force under peacetime conditions.

---

[3] See case study 1.

Absenteeism.—Scheduled workdays lost because of absence from work increased from 6.6 percent to 8.9 percent during the longer workweek.

Output.—Against an increase of weekly hours of 15.6 percent, output increased 13.2 percent. For every 3 hours of additional worktime, output increased by the equivalent of 2½ hours' production under the shorter work schedule.

23: *Workweek of 48 hours* vs. *one of 54 hours, no wage incentives; medium-heavy and heavy operator-paced foundry operations; men.*

This department performed molding and metal-pouring operations in the same foundry which furnished the material for case study 22. The weights handled by workers varied with the size of the castings and ranged from 20 pounds to several hundred pounds. As a rule, all weights above 75 pounds were lifted by means of manually or power operated cranes. Work was usually done in crews of three: a molder, a helper, and a core setter. The molds were assembled from oven-dried cores and backed with sand. When the molds were large—and consequently heavy—the molten metal was poured from crucibles which were transported by crane to the assembly floor. Small molds were moved by crane to the pouring floor where the metal was poured. When the castings had cooled, they were moved to the shake-out floor where a crew of shake-out men removed them from the flasks. The physical demands of the operations may be characterized as medium-heavy to heavy. The work pace was entirely controlled by the operator.

Working conditions and hourly schedules.—Plant conditions were essentially the same in this department as those described in case study 22. Employees were paid on a straight hourly basis. There was no wage-incentive system of any kind.

The schedule in effect through March 1943 was 48 hours a week, or 6 days at 8 hours. In the spring of that year, the scheduled workweek was increased to 54 hours by adding 1 hour to each workday. The average work force decreased from 88 men to 68 men during the longer workweek.

FINDINGS OF STUDY

Efficiency was about 4.1 percent better during the 9-hour day as compared with the 8-hour day. As was found in case study 22, the absence of a wage-incentive system apparently resulted in a pace under the shorter hourly schedule which could be maintained and, in fact, improved even though hours were increased.

Absenteeism increased from 6.9 percent to 8.5 percent when the workweek was lengthened.

The net effect of the increase of 12.5 percent in working hours was an increase of 13.5 percent in over-all output. The increase in efficiency more than offset the increase in the time lost because of increased absenteeism. In terms of hours, the addition of 6 hours to the workweek resulted in an increase of 6½ hours of output.

This study again illustrates that the pace of workers at straight hourly rates was not so fast under a 48-hour schedule but that it could be maintained, and even improved, when hours were increased to 54 per week.

24: *The effectiveness of Sunday work during a 54-hour week* vs. *a 58-hour week without Sunday work, indirect wage incentives; light, operator-paced machining operations; men.*

The operations in this department consisted almost entirely of machining small metal parts for war materials: machine-gun tripods, aircraft parts, and similar equipment. The operations, primarily drilling, grinding, and machining of small aluminum and steel parts, may be characterized as light and operator-paced.

Working conditions.—Working conditions were good. Ventilation was adequate, noise was moderate and lighting varied from adequate to good. There were no fumes or smoke. The wood block floors were kept clean and aisles were usually free of obstructions. Considerable attention was given to safety by management. There was no cafeteria. Lunch tables were provided, and a private caterer brought in hot dishes, sandwiches, etc.

Wage incentives.—The department operated on a measured day-work system. Employees attained specified rates provided they maintained certain prescribed levels of output. Although there was no incentive system in the sense of earnings which fluctuated with the volume of output, the wage system required employees to maintain at least average efficiency in order to qualify for certain wage brackets.

Hourly schedules and shifts.—In 1942, the selected group of 31 experienced male operators were scheduled to work 7 days a week. The schedule called for three nonrotating shifts of 8 hours each, which included a paid lunch period of 15 minutes.

A year later, in 1943, Sunday was eliminated from the schedule, but daily hours were lengthened to 10½ per day, including a paid ½-hour lunch period, with 8 hours on Saturday. The resulting workweek, excluding the lunch period, was 58 hours, as against the earlier 54-hour week. The longer schedule was operated on a two-nonrotating-shift basis.

FINDINGS OF STUDY

Efficiency was higher during the 6-day week than during the 7-day week, although daily hours had been increased from 8 to 10. Average hourly output was 14.3 percent better when there was no Sunday work.

Absenteeism was about the same during both schedules, with an average of about 5 percent. The absence peak during the 6-day week came on Saturday and reflects a desire for a longer weekend.

During the 7-day week, attendance was worst on Sunday, with Monday only slightly better. Operators, working on Sunday, at double pay, frequently took Monday off.

Output.—The longer workweek, with Sunday work eliminated, was more productive than the 7 days at an 8-hour schedule. Although weekly hours had increased by 7.4 percent, output increased by 22.5 percent. With very little change in the absence rate, this increase was due entirely to the improved efficiency during the 6-day week.

By eliminating Sunday work, the plant not only saved the cost of double pay for work on that day but actually gained about 15 percent of output beyond the 7.4 percent of additional hours worked.

25: *Workweek of 37½ hours* vs. *one of 58 hours for men, individual wage incentives; light, operator-paced machining operations.*

This study was conducted in a plant which produced small precision parts for guns and a variety of control devices for lubricating systems. Most of the work involved the operation of metalworking machines such as grinders, millers, drill presses, riveting machines, lathes, and similar equipment. The weight of the parts handled rarely exceeded 5 pounds. The work required a high degree of precision because of the small tolerances allowed on most jobs. The operations surveyed were light and, except for the work at a few automatic machines, were entirely operator-paced.

Working conditions.—Conditions in the plant were good. Lighting ranged from fairly adequate to good. There were no fumes, smoke, or dust. Noise was moderate. Working space was somewhat crowded. A well-equipped first-aid room was staffed with three registered nurses. Rest periods were voluntary and were taken when the work flow permitted.

The work force.—Forty-three experienced male operators were selected for study. Most of them had been employed by the company for many years. A spirit of friendly cooperation between foremen and workers, and among the workers themselves was clearly apparent. Industrial relations were very good.

Wage incentives.—Workers were paid on an individual piece-rate basis. All rates, set by means of time studies, required the approval of the labor organization representing the employees.

Hourly schedules.—The periods compared were January to August 1942, and a comparable period in 1943. During the first period, 3 shifts of 7½ hours each were worked for a workweek of 37½ hours. During the second period, when the plant was entirely on war work, daily hours were increased to 10, with a sixth day of 8 hours added, for a weekly total of 58 hours.

FINDINGS OF STUDY

Efficiency.—In spite of the 54.7 percent increase in hours, the efficiency level during the longer workweek actually increased by 15.3 percent.

Two reasons were advanced by management to explain this experience: (1) The participation of employees in the war effort acted as a powerful stimulus to greater efficiency; and (2) the longer runs on each job during the longer workday spread unproductive time over a longer period of productive effort. Apparently, the work during the longer workweek was not so hard as to induce fatigue serious enough to bring about a slowing down on the part of the workers.

Absenteeism.—The absence rate rose from 2.1 percent to 3.3 percent during the longer workweek. In both periods, the rates were low and were indicative of the effectiveness of a labor-management committee's effort to curb absenteeism.

Output.—The extension of the hourly schedule by 54.7 percent and improved efficiency were responsible for an 81.2-percent rise in total output. In terms of hours, for every hour added to the workweek, approximately 1½ hours of output were achieved.

26: *Workweek of 37½ hours* vs. *one of 54 hours for women, individual wage incentives; light, operator-paced assembling and machining operations.*

The performance of 25 experienced female operators was surveyed in the same plant which furnished the data for case study 25. The group was engaged in assembling, with the aid of light hand tools, the small parts described in the previous case study. A small percentage of the women performed light machining operations.

Working conditions, pay incentives, and worker-management relations were identical with those described in case study 25.

Hourly schedules.—The scheduled workweek was lengthened in 1943 from 37½ hours (5 days at 7½ hours), to 54 hours (3 days at 10 hours and 3 days at 8 hours).

FINDINGS OF STUDY

Efficiency.—A comparison of labor performance during both schedules reveals an experience similar to that found in the previous case study. The change in hours represented an increase of 44 percent. The workers, however, were 16.9 percent more efficient during the longer workweek. The reasons advanced for the comparable reaction in the analysis of case study 25 also apply here.

Absenteeism rose slightly from 3 percent during the 37½-hour schedule to 3.3 percent during the longer workweek.

The combined effect of an increase of 44 percent in scheduled working hours, stable attendance, and improved efficiency was an increase of 67.6 percent in output. Stated differently, for every hour added to the workweek about 1½ hours of output were gained.

27: *Irregular overtime* vs. *a fixed 8-hour daily schedule with occasional Sunday work for men, individual wage incentives; light to medium-heavy, operator-paced machining operations.*

The operations studied in this plant consisted of machining processes on lathes, mills, grinders, and similar metalworking machines. The material handled varied in weight from one pound to over 100 pounds. Heavier pieces were lifted with the aid of mechanical hoisting equipment. The operations were largely operator-paced and afforded very little idle time to the workers.

Working conditions.—Working conditions in the plant were good. Work space and aisles were adequate. Noise was moderate. There were no fumes or dust. The fluorescent installation provided adequate light. Rest rooms including shower facilities were clean and ample in number. Well-prepared lunches were served at nominal prices in the plant cafeteria. Industrial relations were good.

Wage incentives.—An incentive system based on standards established through time studies, provided for additional pay for work done in less than standard time. Operators were paid at their hourly rate for all minutes "saved."

Hourly schedules.—The performance of 29 experienced male operators who worked in the department under both schedules were studied. The working schedules compared were those existing during the first 6 months of 1941, and the same period in 1943. During the first period, the nominal workweek was 6 days at 8 hours. Actually, however, daily hours usually varied between 8 and 10 and occasionally went as high as 15. During the second period, the irregular overtime had been replaced by Sunday work, with the requirement that each operator work two Sundays a month. The purpose of the survey, therefore, was to determine the desirability of working a fixed 8-hour daily schedule which included two Sundays a month as against sporadic overtime which, on occasion, stretched the day to 15 hours.

FINDINGS OF STUDY

In evaluating the changes in efficiency and output it must be borne in mind that the first period preceded our entry into the war and that the second period involved direct participation in the war effort. Unquestionably, the results reflect the effect of war morale, although the extent of this cannot be measured.

Efficiency.—Even though weekly hours increased slightly by 4.7 percent from an average of 51.5 hours during the prewar period to 53.9 hours during the war period, labor efficiency increased by 16.3 percent.

Absenteeism.—Time lost from work because of unauthorized absence amounted to only 3 percent during the first period. With the change to Sunday work, the rate more than doubled to 7.2 percent.

Output.—The net effect of greater efficiency, a higher absence rate and a slightly longer workweek was an increase of 16.6 percent in total output. The primary reasons for the better output record appear to be: (1) The regular work schedule, although it meant work on two Sundays during each month: and (2) the psychological impetus of participation in the war effort.

28: The effectiveness of Sunday work for women, individual wage incentives; light, operator-paced machining operations.

The department surveyed in this study is in the same plant discussed in case study 27. All of the 22 employees were engaged in light metal-machining operations and were women. The material handled varied in weight from one ounce to several pounds. The work may be characterized as light operations at operator-paced metalworking machines.

Working conditions and wage incentives were the same as those described in case study 27.

Hourly schedules.—In 1943, the nominal workweek consisted of 6 days at 8 hours each, which included a paid ½-hour lunch period, and, in addition, work on two Sundays a month. The average workweek consisted of 52.5 hours. In 1944, Sunday work had been discontinued and the workweek consisted of 6 days of 8 hours each for a total of 45 actual hours of work.

FINDINGS OF STUDY

The purpose of the survey was to measure the effect of the discontinuance of Sunday work on two Sundays a month, with the reduction of total weekly hours from 52.5 to 48, each period including a paid ½-hour lunch period.

When Sunday work was dropped from the schedule, the hourly rate of output increased by 22.9 percent. It is significant that the change in nominal weekly hours consisted of a reduction of only 4½ hours, from 52½ to 48, or only 9 percent. Apparently, the important point is that the change involved the complete elimination of Sunday work for the women operators.

Efficiency.—Another factor, but of unmeasurable effect, was that the reduction in schedule followed D-day (June 1944). This may have stimulated efficiency beyond the effect of the dropping of Sunday work. The data indicate, however, that the effect of this shot in the arm—if it was one—continued unabated, for hourly efficiency was as good in December as it had been in July, the month immediately after D-day.

Absenteeism.—Unauthorized time lost from work decreased from 10.9 percent to 7.4 percent.

Output.—The combined effect of increased efficiency and improved attendance was an increase in total output of 16.7 percent. Thus, although the workweek was reduced 4½ hours by the elimination of Sunday work, total weekly output was increased by the equivalent of almost 9 hours.

Daily Pattern of Efficiency and Absenteeism

The data permitted the determination of daily patterns of efficiency and absenteeism. During the longer workweek, efficiency was lowest on Sunday, slightly better on Monday, and then rose to a better level which was fairly well maintained through Friday. On Saturday, however, it dropped again to about the Monday level.

During the shorter workweek, hourly efficiency was best on Monday and was maintained at a slightly lower level for the rest of the week. The efficiency level for every day in the week was substantially higher during the shorter week than during the period with Sunday work.

Absenteeism was markedly lower during the shorter workweek on each day except Monday; and even on that day it was slightly lower.

The outstanding feature of the absenteeism pattern for the period with Sunday work is the low absence rate on Sunday—when work was paid at double rates because it was the seventh day in the week. But workers tended to make up for this by taking time out on other days of the week, notably on Monday and Wednesday.

The pattern for the 48-hour, 6-day week reveals a tendency to stretch the week end by taking off either Monday, or, to a lesser extent, Saturday. Many of the operators studied, however, were married women with home duties, a fact which may explain this pattern even under the 48-hour week.

29: *Workweek of 58 hours* vs. *one of 50 hours, and the effects of reductions in the work force, for men, individual wage incentives; medium-heavy, operator-paced machining operations.*

This plant produced textile manufacturing machinery. Operations involved work on metalworking machines, such as lathes, drills, and milling machines. A high degree of precision was required, as tolerance allowances were very small. The work may be characterized as medium-heavy, operator-paced machining operations.

Working conditions.—Plant conditions generally were good. Ventilation and lighting were adequate. There were no fumes or dust. Noise was moderate. Aisles were wide and clearly defined. Housekeeping in general was good.

The work force.—The period surveyed involved a reduction in the work force as well as in work hours. Average employment in the plant dropped from about 500 to about 325. A high percentage of the operators were highly skilled on a number of operations.

Wage incentives.—The wage-incentive system consisted of an individual premium for time saved from standard time allowed, in addition to the standard hourly rate.

Hourly schedules.—Findings are for a selected group of 33 male operators who changed from a 58-hour workweek of 5 days at 10 hours and Saturday at 8, to a 50-hour week with Saturday work eliminated.

FINDINGS OF STUDY

Efficiency.—Efficiency was 5.4 percent poorer under the 50-hour week than it had been under the 58-hour week. Apparently this drop was the result of fear concerning the cut-back in the work force which was occasioned by the reduced volume of work available. The change in efficiency appears to be attributable to a stretching of available work rather than to the change in hours.

Absenteeism.—Elimination of Saturday work had only a slight effect on absenteeism. The change was from 3.6 to 3.2 percent, which points up a successful effort by the company to keep absenteeism down during the longer workweek.

Output.—The combined effect of the 15.3-percent decrease in hours, the lower efficiency, and the nearly constant absenteeism rate, was a reduction in output of 19.2 percent. Thus, the 8 scheduled hours saved by eliminating Saturday work resulted in a loss of the equivalent of 11 hours of output.

30: *The effects of changes in hours and improvements in working methods for women, day shift, individual wage incentives; light, operator-paced machining operations.*

This plant manufactured air brakes. The women in the department studied were on machining operations, such as broaching, boring, grinding, and drilling on small stock. The work may be characterized as light, operator-paced machining operations.

Working conditions.—The plant was air-conditioned. There were no fumes, smoke, or dust. Fluorescent lighting was good. Noise was moderate. Equipment was in excellent condition, and was well-guarded. Aisles were narrow but adequate.

Wage incentives.—Workers in this department worked under a wage-incentive system. Earnings were based on the percentage which actual production was of standard output, as determined by time studies. However, workers were not paid for additional output beyond 125 percent of the standard. Few workers reached the upper limit.

Hourly schedules.—The experience of a selected group of 10 women on the day shift was studied at three distinct hourly levels. In the first period the workweek consisted of 6 days at 7⅔ hours, or 46 hours. This was followed by a workweek of 50 hours comprising 5 days at 10 hours. In the succeeding period a sixth day of 8 hours was added for a total workweek of 58 hours.

FINDINGS OF STUDY

Efficiency.—When the workweek was raised from 48 to 50 hours, but with Saturday work eliminated, the efficiency rate went up 9.5 percent. When the workweek was lengthened by the addition of a sixth day of 8 hours, efficiency rose another 10.9 percent. The net increase over the original 46-hour week was 21.4 percent. The better efficiency of these workers during the longer hours, however, was not due to better performance, but to the fact that management introduced changes which enabled workers to spend nearly all their time at their equipment. These changes consisted of the addition of separate groups of workers to perform such tasks as getting or removing materials, work previously performed by the operators. Consequently all of the operators' time was productive time.

Absenteeism.—The elimination of the sixth day of 7⅔ hours with the increase from 7⅔ to 10 hours for the other 5 days of the week, was accompanied by an increase in the rate of absenteeism from 4.9 to 8.3 percent. But when Saturday was again added to the schedule with the maintenance of the longer workday, absenteeism rose still further, to 15.4 percent.

Output.—The 8.7-percent increase in the workweek from 46 to 50 hours, brought about an increase in total weekly output of 14.9 percent, an increase of about 1¾ output hours for each hour added to the schedule. When an

8-hour Saturday was re-introduced, the increase of 26.1 percent over the 46-hour schedule was accompanied by a rise of 36.4 percent in output, adding almost 1½ output hours for each hour added to the workweek. Thus, in spite of considerable increases in the absenteeism rate, output increased markedly during the longer workweek. As indicated, however, the increase was due to managerial changes in the method of operation. This study demonstrates that it is possible, by means of such changes, to overcome the usually adverse effect of substantially higher work hours.

31: The effects of changes in hours and improvements in working methods for women, night shift, individual wage incentives; light, operator-paced machining operations.

The workers in this study were employed in the same department and on the same operations as those in case study 30. Working conditions and wage incentives were similar.

Hourly schedules.—The findings are for a selected group of 10 women. During a workweek of 6 days at 7⅔ hours, or 46 hours, they worked on an afternoon and a night shift. When Saturday was eliminated and daily hours increased to 10, lengthening the workweek to 50 hours, the two shifts were combined into one night shift. In a third period, an 8-hour Saturday was re-introduced, making a 58-hour workweek.

FINDINGS OF STUDY

Efficiency.—When the workweek was changed from 46 to 50 hours, efficiency increased by 19.9 percent. When the 8-hour Saturday was added, there was practically no change in efficiency, the level being 0.2 percent higher. Compared with the original 46-hour workweek, efficiency during the last period was 20.1 percent higher. The increase was not due to better performance under the longer schedules, but was brought about by the introduction of more workers to take care of indirect labor tasks, allowing the operators to spend nearly all their time on actual production.

Absenteeism.—During the 46-hour workweek absenteeism was 5.7 percent. With the workweek reduced to 5 days, but with daily hours lengthened from 7⅔ to 10, the rate rose somewhat, to 6.8 percent. When the 8-hour Saturday was added, it again rose, to 7.7 percent.

Output.—The 8.7 percent increase in hours, from 46 to 50 per week, brought about a rise of 28.8 percent in output. In terms of hours, the 4 hours added to the workweek resulted in 13¼ additional hours of output. The increase in the schedule of 26.1 percent, by the change from 46 to 58 hours per week, was accompanied by a 48.2-percent rise in output, or an increase of 22 hours of output for the 12 additional scheduled hours. The greater increases in output in comparison to hours were the result of the changed work-flow methods which made for better utilization of productive time.

32: *The effects of changes in hours and improvements in working methods for men, day shift, individual wage incentives; light, operator-paced machining operations.*

The men in this study worked in the same department, and on the same operations as the women in case study 30. Working conditions and wage incentives were similar.

Hourly schedules.—The experience of a selected group of 15 men on the day shift was studied under two levels of scheduled hours. In the first period the workweek consisted of 6 days at 7⅔ hours, or 46 hours. In the second period daily hours were lengthened to 10 for 5 days, and Saturday was maintained as an 8-hour day. There was also frequent work on an 8-hour Sunday. The average workweek during this period was 61 hours.

FINDINGS OF STUDY

Efficiency rose 8 percent during the longer workweek, as the result of the addition of indirect labor workers, allowing the operators to spend almost all of their time on actual production.

Absenteeism rose from 3.5 to 5.7 percent when the workweek was lengthened.

Output.—The increase in the workweek from 46 hours to an average of 61 hours, a rise of 32.6 percent, brought about a 39.9-percent increase in output. Thus the improvement in working methods served to add 18⅓ output hours when an average of 15 hours was added to the workweek.

33: *The effects of changes in hours and improvements in working methods for men, night shift, individual wage incentives; light, operator-paced machining operations.*

This study covers the experience of men on a night shift in the same department and on the same operations as the women in case study 30. Working conditions and wage incentives were similar.

Hourly schedules.—The findings are for a selected group of 15 men under two levels of hours. During the first period, when the workers were divided between an afternoon and a night shift, the schedule consisted of a 46-hour workweek of 6 days at 7⅔ hours. In the second period the two shifts were combined into one night shift, and the schedule was lengthened by increasing daily hours to 10 for 5 days, maintaining Saturday as an 8-hour workday, and by scheduling a frequent 8-hour Sunday. The average workweek during this period was 61 hours.

FINDINGS OF STUDY

Efficiency.—There was an increase in efficiency of 13.3 percent during the period of the longer workweek, resulting from the elimination of unproductive labor by the operators.

Absenteeism was 3.9 percent during the 46-hour workweek. The rate rose to 6.7 percent under the longer schedule.

Output.—The 32.6 percent increase in hours from 46 to an average of 61 per week was accompanied by a 45.9-percent increase in output. The addition of an average of 15 scheduled hours per week thus effected an increase of about 21 hours of output.

34: *The effects of changes in hours and improvements in working methods for men, group wage incentives; light, operator-paced assembling and testing operations.*

The men in this study worked in the same plant, but in different departments from the women in case study 30.

Operations consisted of assembling and testing the parts machined in the previous department. The work may be described generally as light, operator-paced assembling and testing operations.

Working conditions.—Working conditions were similar to those in the other department.

Wage incentives.—The wage-incentive system worked on the same principle as in the previous department, except that the workers were paid on the basis of group efficiency. This was done because operations were interdependent.

Hourly schedules.—The experience of a selected group of men in four assembling and testing departments, on day and night shifts, was studied under two levels of hours. During the first period the schedule consisted of 6 days at 7⅔ hours, or 46 hours. In the second period daily hours were increased to 10, for 5 days, and Saturday was maintained as an 8-hour day, making a 58-hour workweek.

FINDINGS OF STUDY

Efficiency increased 7 percent during the longer workweek. The better efficiency level, despite the longer hours, was the result of improvement in working methods, allowing productive workers to spend almost all their time on actual productive operations.

Absenteeism rose from 2 percent to 4.2 percent when the workweek was extended from 46 to 58 hours. During both periods the level was low.

Output.—The 26.1-percent increase in scheduled hours was accompanied by a 31.9-percent rise in output, or an addition of 14⅔ output hours for the 12 hours added to the schedule.

35: *Workweek of 54 hours* vs. *one of 61½ hours, individual wage incentives; light, operator-paced machine and bench operations in the manufacture of dental equipment; men and women.*

The operations studied were partly performed on machines—such as lathes, grinders, and polishers—and partly consisted of bench assembling. The weights of pieces handled varied from less than an ounce to one pound. All the work was light, and essentially operator-paced, with very little waiting during machine processing. The work required very close tolerances. The product was dental equipment throughout the entire war period.

Working conditions.—Plant conditions were good, work space was adequate and aisles were wide and unobstructed. There were no fumes or dusts, and ventilation was good. Lighting was only fair. Noise was of moderate volume. Washroom facilities were good. The cafeteria was adequate in size. Workers took voluntary rest periods amounting to about 25 minutes per day.

Machinery was well guarded. Safety conditions were good, as was the plant's accident record.

The work force.—The shop employed about 150 workers. About one-quarter of the work force was composed of women who were mostly engaged in packing and shipping operations. The majority of the workers had long service records with the company and were highly skilled in their work.

Wage incentives.—Workers were paid under a piece-rate system with a guaranteed hourly rate. Rates were determined by means of time studies.

Hourly schedules and shifts.—In 1942, the company shifted from a 40-hour, 5-day week, to a 54-hour week of 6 days at 9 hours. In the following two years, hours were again increased to a 61½-hour week by lengthening daily hours to 10½ for 5 days and retaining Saturday at 9 hours. This schedule proved to be too strenuous for many workers and management permitted a choice between working 54 or 61½ hours a week. Only 16 workers could be found who had consistently worked the 54-hour schedule and the subsequent 61½-hour schedule. The resultant findings consequently are biased in the direction of understatement, as the sample consisted only of those workers who found the 61½-hour schedule not too fatiguing. Only one shift was operated throughout the entire period surveyed.

FINDINGS OF STUDY

Efficiency.—When the 6-day schedule was increased from 54 to 61½ hours a week, the average hourly efficiency was reduced by 4.3 percent. It is entirely probable that the longer schedule would have resulted in a considerably larger drop in efficiency had the entire shop been required to work the 61½-hour schedule.

Although no data were available for performance under the 40-hour week, it was noted that the efficiencies of the 16 selected men dropped sharply during the first 2 months under the 54-hour schedule. As the level at which efficiency stabilized under the 54-hour week was lower than the efficiencies during the two transitional months following the 40-hour week, there is good reason to believe that the efficiency level during the short workweek had been considerably better than that which prevailed during the 54-hour schedule. The data for the first 2 months under the 54 hours suggest that the drop in efficiency from that which had prevailed during the 40-hour week was at least 5 percent. When hours were raised to 61½, efficiency decreased again by 4.3 percent. There also was some evidence that time standards had been loosened under the 61½-hour schedule, as an additional incentive to the operators to work this schedule. This again indicates that the measured decrease of 4.3 percent in hourly efficiency understates the actual decrease. Indications are that the efficiency level for the observed operators was at least 10 percent poorer at the 61½-hour level than at the 40-hour level, and that this decrease would have been greater if the entire work force had been required to work the longer schedule.

Absenteeism.—Absenteeism increased gradually during the 54-hour week and stabilized at an average rate of 5.1 percent. The percentage of scheduled time lost increased still further when weekly hours were raised to 61½, the average absence rate stabilizing at 6.3 percent. Absenteeism, like efficiency, probably would have been higher had the sample included those men who found this schedule too strenuous and therefore confined themselves generally to a workweek of only 54 hours.

Output.—Lowered efficiency and increased absenteeism were reflected in the rise in output by only 4.2 percent when hours were increased by 13.9 percent for the 61½-hour week. Thus, it took slightly more than 2 hours to bring about the addition of 1 hour's production. The additional output gained under the 61½-hour schedule could have been produced in 56 hours, had the efficiency and absenteeism remained as under the 54-hour schedule.

Daily Pattern of Efficiency and Absenteeism

The daily efficiency levels were about the same for each of the first 5 days under the 9-hour schedule. Only the sixth day, Saturday, showed a poorer performance.

The daily efficiency levels under the 10½-hour day were decidedly lower than those under the 54-hour schedule. However, it is difficult to explain the constant rise for almost every successive day under the longer schedule. The better performance on Saturday, on the other hand, may be due to the fact that it was 1½ hours shorter than the schedule on the other workdays.

The daily absenteeism patterns under the two sets of hours were very much alike, except that the absenteeism rates under the long hours were at higher levels during the first two and last two days of the week. The difference was particularly marked on Saturdays. Under both levels of hours, the absenteeism rate dropped fairly steadily from Monday through Thursday, and then rose again on Friday, with a high peak on Saturday.

36: 6-day week vs. *5-day week for night work of biweekly rotating shifts; individual wage incentives; medium-heavy, operator-paced machining operations; men.*

The department was engaged in the production of 105 mm. shells and 60 mm. mortars, which involved metalworking processes on lathes, millers, thread millers, and automatic screw machines. The work was medium-heavy. It was operator-paced and afforded little or no resting time for the operators during processing operations. The weight of materials handled varied from less than 1 pound to 47 pounds for the completed shell.

Working conditions.—The workshop was free from fumes and dust. It was clean and well-ventilated. Lighting was good, and noise moderate. With the exception of a few crowded places, working areas were adequate and aisles wide and unobstructed. Clean-up facilities and lockers also were adequate and well-kept. Lunches were served in a cafeteria. The plant appeared to maintain very good safety conditions.

The work force.—All of the 17 operators studied in this survey were white males in the middle age groups.

Wage incentives.—The wage incentive consisted of payment for all standard minutes earned in excess of minutes worked. Standards were developed on the basis of time studies.

Hourly schedules and shifts.—Operators worked alternately two weeks on the day shift and two weeks on the night shift. Throughout the selected period, the day-shift schedule remained at 58 hours per week, with 10-hour days for 5 days and 8 hours on Saturday. During the first half of this period, the night shift worked 63 hours per week, consisting of 5 days at 11 hours and 8 hours on Saturday. During the second half, the night shift went on a 60-hour schedule by working 5 days at 12 hours and eliminating Saturday work.

There were no organized rest periods, though an estimated average of ¼ to ½ hour of voluntary rest was taken each day. There was a ½-hour lunch period.

FINDINGS OF STUDY

Efficiency.—During the period of a 5-day night schedule and a 2-day weekend, the efficiency of the 17 men studied increased by 6.1 percent. This result was achieved by lengthening the hours for the night shift from 11 per night to 12 and by eliminating Saturday work, even though the shortened workweek came only in 2 weeks out of 4. As already indicated, the men worked 6 days during the 2 weeks on the day shift.

Absenteeism.—The 2-day weekend for the night shift also resulted in decreasing time lost due to absenteeism from 7.9 percent of the scheduled work hours to 6.1 percent.

Output.—Increased efficiency and decreased absenteeism resulted in an over-all output increase of 4.3 percent, even though the average weekly schedule for both the day and night shift combined decreased by 3.4 percent. The survey indicates that it was possible to increase output, in spite of long weekly and daily hours, by introducing a 2-day weekend in 2 weeks out of every 4.

37: Workweeks of 40 hours vs. *48 (6 days)* vs. *48 (5½ days)* vs. *54 (6 days), group wage incentives; light, operator-paced hand composition of printing type; men.*

The work in this plant consisted of hand composition of type for printing office supplies. The work was light and entirely operator-paced, each man working on an individual assignment. The general pace of work in this plant was moderate. The operations required exacting workmanship.

Working conditions.—Physical working conditions in the plant appeared to have changed very little during the last 20 years and were far from modern. Lighting ranged from poor to adequate and a general atmosphere of gloom prevailed. Ventilation was adequate because of the large amount of wall space devoted to windows. The plant was relatively free from heat, dusts, fumes, or gases. Temperatures were moderate even during the summer. There was little noise. The operations, generally, were clean and necessitated only limited washroom facilities. There were no organized rest periods and no eating facilities of any kind. In spite of the crowded shop conditions, housekeeping was good enough to prevent injury hazards from this source. The operations themselves were not hazardous.

The work force.—Although the size of the department was small, the composition of the work force had remained practically unchanged throughout the entire 3-year period surveyed. Most operators, including the 9 men selected for this survey, had been with the company for many years. Turnover was very low.

Wage incentives.—The department operated on a group wage-incentive system. The efficiency rate was developed from a comparison of total hours earned during each week with the total hours required under the time standards for the work performed during the week. The excess hours were paid at regular or at overtime rates for regular or overtime hours respectively. There were no artificial ceilings to incentive earnings.

Hourly schedules.—The department worked only one shift. The selected period extended from January 1942 to February 1945. During all of this time the plant was engaged in war work.

The work schedule was changed from 40 hours a week (5 days at 8 hours each) to 48 hours by the addition of an 8-hour Saturday. Then, the sixth day was shortened to 4 hours, but the 48-hour week was maintained by increasing hours on the other 5 days to 8.8 per day. Finally, daily hours were raised to 9 on every day for a total of 54 per week.

FINDINGS OF STUDY

The 48-hour week—6 days.—For the 9 men studied in this department, the change from 5 days at 8 hours to 6 days at 8 hours resulted in a slightly better efficiency (1.4 percent) as well as an absenteeism rate slightly lower (0.5 percent) than the very low rate which had prevailed during the 40-hour week (1.4 percent). As a consequence, the 20-percent increase in hours was more than matched by a 22.8-percent increase in total weekly output.

The 48-hour week—5½ days.—When the 48-hour week was worked in 5½ days, efficiency increased still more, and averaged 4.7 percent above that for the 40-hour level. Concurrently, however, there appeared to have been a greater tendency to prolong the week end by taking off the half day, for absenteeism rose to 4.4 percent. Increased absenteeism offset the rising efficiency enough to reduce weekly output slightly, but still leaving it at 21.6 percent above that for the 40-hour level. In comparison, hours had been increased 20 percent.

The 54-hour week—6 days.—The change to a 6-day week at 9 hours, how-ver, resulted in an average efficiency level lower than that of any of the horter schedules, and 3.2 percent below that for the 40-hour level. Although he absenteeism loss dropped slightly, to 3.8 percent, the total output was nly 27.6 percent better under the 54-hour week as against the 35-percent ncrease in hours above the 40-hour week.

In terms of the 8-hour day and 6-day week, the additional hours worked uring the 9-hour-day schedule of the same number of days per week netted nly 2 more hours of output.

8: *Workweeks of 40 hours* vs. *48 (6 days)* vs. *48 (5½ days)* vs. *54 (6 days), group wage incentives; light, operator-paced packing operations; women.*

This is another department of the same plant described in the preceding ase study, 37. Except for the points cited below, the data presented in he preceding case study also apply to this department.

The work involved counting, assembling, and preparing cardboard fold-rs for shipment. Work was light and entirely operator-paced, and was done n a day shift. The group consisted of 8 women. The changes in weekly hours heduled were the same as in the preceding study.

NDINGS OF STUDY

The 48-hour week—6 days.—The change from 5 to 6 days at 8 hours from 40 to 48 per week) resulted in a slight decrease in efficiency, 0.4 per-ent. Time lost because of absenteeism, however, more than doubled, rising om 3 percent to 6.8 percent. As a result, weekly output rose by 14.9 per-ent against an increase in hours of 20 percent.

The 48-hour week—5½ days.—When daily hours were lengthened to 8.8 er day so as to provide for a 4-hour Saturday while still maintaining the 8-hour week, efficiency improved and was 2.3 percent better than it had een at 40 hours. But the shortened Saturday seemed to invite taking that ay off. Absenteeism rose to 11.8 percent, nearly 4 times what it had been at 0 hours. The higher absenteeism offset the improved efficiency to the extent hat total output dropped 2.8 percent below the level obtained during six -hour days for the same total weekly hours. As against the 40-hour week, he 20-percent increase in hours brought about 11.7 percent more output.

The 54-hour week—6 days.—When hours were raised to 9 per day for a otal of 54 per week, efficiency went up again, to a level of 3.1 percent better han that of the 40-hour week and about 3.5 percent better than during the 8-hour week, with 6 days at 8 hours. But absenteeism went up still further, o 14.4 percent—nearly 5 times what it had been during the 40-hour week. s a consequence, the 35-percent increase in scheduled hours, from 40 hours o 54, resulted in only 22.6 percent more output. In other words, it took 3 ours to produce 2 more hours of output.

39: *Workweeks of 48 hours (6 days)* vs. *48 (5½ days)* vs. *54 (6 days), group wage incentives; medium-heavy, operator-paced shipping operations; men and women.*

This department belonged to the same plant described in case study 37. Cartons and boxes were received by means of conveyor chutes or elevator and were prepared for shipping. Light trucks were used to handle the heavier boxes. The weight of materials handled varied from light to medium. All work was paced entirely by the operators. The group studied consisted of 4 men and 4 women.

No data were available for the 40-hour week. The rest of the schedules worked in this department were the same as those cited in case study 37. All work was done on a day shift.

FINDINGS OF STUDY

The 48-hour week—6 days.—The change in the daily pattern of the 48-hour week, from 6 days at 8 hours to 5 at 8.8 and 1 at 4, resulted in a spurt of 9.4 percent in efficiency, while the rate of absenteeism remained unchanged, at about 7.5 percent. Consequently, there was a net gain in output of 9.6 percent even though weekly hours remained unchanged.

The 54-hour week.—When hours were lengthened to 9 per day for 6 days and weekly hours were increased to 54, nearly half of this increase in efficiency was lost. However, the efficiency level still remained 5.3 percent better under the 9-hour day than it had been under the 8-hour day. For some reason, however, and differing sharply from the experience in the other departments studied, absenteeism resulted in only 5.9 percent of lost time.

The net effect of the 12.5-percent increase in hours during the 54-hour week, as compared with the 48-hour week and 8-hour day, was an increase in output of 20.5 percent.

40: *Workweeks of 48 hours (6 days)* vs. *48 (5½ days)* vs. *54 (6 days), day shift, group wage incentives; light, operator-paced assembling operations; women.*

This study follows the performance of 5 women in another department of the same plant described in case study 37. The workers were engaged in punching and inserting metal or plastic tabs into slotted folders. The work was entirely operator-paced, with the pace fast and steady. The operations were light, repetitive, monotonous, and did not require any special skill. Operators performed their work while seated at benches. With the exception of the 40-hour schedule, for which data were no longer available in this department, the weekly schedules worked were the same as those of case study 37.

FINDINGS OF STUDY

The 48-hour week—6 days vs. *5½ days.*—The change from a 48-hour week of 6 days and 8 hours per day to one of 5 days at 8.8 hours and 1 at 4, resulted in a slight improvement in efficiency—0.3 percent. The high rate of absenteeism during the 8-hour, 6-day week, 22.1 percent, dropped to 12.5 percent under the new schedule. As a consequence, the simple change from a 6-day week to a 5½-day week, with weekly hours remaining at 48, brought about an increase in weekly output of 12.8 percent on the day shift.

The 54-hour week.—The lengthening of daily hours to 9 for a 6-day week of 54 hours, resulted in a net loss in efficiency of only 0.5 percent. The absenteeism loss increased only slightly, from 12.5 percent to 13.2 percent.

As a consequence, the increase in hours of 12.5 percent to the 54-hour week resulted in a net gain in output of 25 percent.

41: Workweeks of 48 hours (6 days) vs. *48 (5½ days)* vs. *54 (6 days), night shift, group wage incentives; light, operator-paced assembling operations; women.*

This department represented, in essence, the night shift of the small department described in case study 40. The work of the 5 women on the night shift was the same as that of the day shift. Working conditions and wage incentives were the same as those described in case study 37. Data were no longer available on the 40-hour week.

FINDINGS OF STUDY

The 48-hour week—6 days vs. *5½ days.*—The first change observed was from 6 days at 8 hours to 5 at 8.5 and 1 at 5.5, but maintaining the 48-hour week. As a result of this change, efficiency improved slightly, 1.1 percent. The high absenteeism loss of 18.5 percent, however, improved decidedly under the new daily pattern, dropping to 5.5 percent. The combined effects of improved efficiency and greatly reduced absenteeism resulted in an increase in total weekly output by 17.3 percent, even though weekly hours remained unchanged.

The 54-hour week.—The next change in weekly hours to 6 days at 9 hours for a 54-hour week actually resulted in better efficiency on the night shift, rising to 1.7 percent above that for the 6-day week of 8 hours a day. On the other hand, however, the absenteeism loss for the night shift during the 54-hour week rose sharply to 22.3 percent.

As a consequence of the steep rise in the absenteeism, the net gain in output was only 9 percent for the night shift, whereas hours had been increased by 12.5 percent.

42: Workweeks of 48 hours (6 days) vs. *48 (5½ days)* vs. *54 (6 days), group wage incentives; light, operator-paced cutting and packing operations; women.*

This is the last of six studies conducted in the plant described in case study 37. Work in this department was operator-paced and very light. It consisted of cutting and packing celluloid signals, tabs, and corner reinforcers. The department consisted of 15 women whose length of service with the company ranged from 5 to 23 years. Most of these women had worked together for more than 10 years. The weekly and daily schedules worked were the same as those described in case study 37, except that the 40-hour period could no longer be studied. All other data pertaining to this plant were cited in case study 37.

FINDINGS OF STUDY

The 48-hour week—6 days vs. *5½ days.*—As in the other departments already discussed, weekly hours were maintained at 48 by increasing daily hours from 8 to 8.8, with 4 hours on Saturday, while reducing the days worked from 6 to 5½. As a result of this change, efficiency improved by 2.7 percent and absenteeism losses were reduced from 8 percent to 4.7 percent.

The 54-hour week.—When hours were increased to 9 per day for a straight 54-hour week, efficiency increased still further, to 5 percent above the 6-day, 48-hour week. But absenteeism losses reverted to nearly the same rate as those for the former 6-hour day by rising to an average of 8.3 percent.

Because of the higher efficiency, however, total weekly output was better by 17.8 percent, as against an increase of weekly hours of 12.5 percent over the 6-day, 48-hour week.

43: *Workweek of 40 hours* vs. *one of 44 hours, day shift, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves; women.*

The operation studied consisted of machine-stripping the center stem from tobacco leaves in a cigar manufacturing plant. The stripping machine is controlled by foot pedals and is fed by hand. The work is done in a sitting position. The operational cycle consists of spreading out the wrinkled tobacco leaf and feeding it into the machine by holding it with both hands. The two halves of the leaf are separated from the center stem by passing the latter between the two cutting edges attached to the center of the rollers. One worker operated one machine.

The work was completely operator-paced, light, repetitive, and monotonous. Care not to tear or cut the tobacco leaves, attention and coordination of both hands and feet imposed a strain on eyes and nerves. The steady and fast pace was primarily due to the continuity of the workflow, the rhythmic nature of the operation, the direct relationship of the amount of output to the operator's earnings, and a moderate work schedule averaging not more than 44 hours per week.

Working conditions.—The stripping department was only moderately noisy. Although air conditioning kept the temperature warm and humid at all times, for the proper conditioning of tobacco, the temperature was not uncomfortable. Lighting was good. Dust was kept at a minimum. Adequate safety aisles and work space, and proper safeguards on moving parts of machines, made this a nonhazardous operation. The first-aid room was well staffed and equipped. Two cafeterias, restrooms, and lockers provided for the employees' comforts. Smoking was forbidden in work areas.

The work force.—The department contained about 500 stripping machines operated by Negro women on fixed day and night shifts. The sample selected for this study consisted of 40 women on the day shift, whose performance was followed from June 1941 to September 1945. A training period of 3 to 4 weeks was considered sufficient to turn out an experienced stripping-machine operator.

Wage incentives.—Each operator was on piecework and was paid by the number of trays of tobacco leaves stripped. Earnings averaged 55 to 65 cents an hour. There was no ceiling on earnings.

Hourly schedules.—An unusual pattern of daily hours was worked, designed to meet the needs of women with home responsibilities, such as caring for children after school hours.

During the 40-hour week, the fixed day shift worked 6 days a week—3 days at 8 hours, 2 at 6, and 1 at 4. During the 44-hour week, the same shift worked 5 days at 7½ hours and 1 at 6½.

There were no organized rest periods. One-half hour was allowed for lunch.

FINDINGS OF STUDY

40 hours vs. *44 hours.*—As already indicated, the change from 40 to 44 hours a week was accomplished by changing the daily schedule from 3 days at 8 hours, 2 at 6, and 1 at 4 to a schedule of 5 days at 7½ hours and 1 at 6½.

The first 6 months at 44 hours showed no change in the hourly performance or in the percentage of scheduled time lost because of absenteeism. During the succeeding months at 44 hours, efficiency increased by 3 percent above the 40-hour level, but absenteeism increased still more sharply, from 1.9 percent at 40 hours to 7.3 percent at 44. The gain in efficiency was offset by the increase in the absence rate, so that output increased only 7.4 percent against an increase in hours of 10 percent. In other words, the 4 hours added to the 40-hour schedule resulted in only 3 hours of additional output.

Sporadic overtime up to 48 hours a week was found during part of the 44-hour period, resulting in an average workweek of 44½ hours as compared with one of 43½ hours for the balance of the period of longer hours. While the absenteeism loss at 44½ hours remained the same as at 43½ hours, efficiency dropped 2.4 percent.

Injuries.—Information was available only for a combination of disabling injuries and first-aid cases, under 44 hours. The weekly rate of injury cases per 1,000 workers was 11 for the day shift. After Monday, the rate increased up to Thursday, then dropped slightly on Friday, and reached the lowest point of the week on Saturday, which was a short workday.

44: *Workweek of 40 hours* vs. *one of 43½ hours, night shift, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves; women.*

The fixed night shift belonged to the same department described in the preceding case study, 43. Only those factors will be cited here in which the night shift differed from the preceding day-shift study.

The 26 Negro women selected for this study worked a weekly schedule of 40 hours (3 days at 5⅚ hours, 2 at 8½, and 1 at 5½) and a schedule of 43½ hours (5 days at 8⁷⁄₁₀ hours) during the survey period from June 1941 to September 1945.

FINDINGS OF STUDY

The 40-hour week vs. *43½ hours.*—During the first 6 months of 43½ hours, the night shift maintained the same rates of efficiency and absenteeism which had prevailed under the preceding 40-hour schedule. Thereafter, efficiency increased by an average of 2.1 percent. (During both the 40- and 43½-hour workweeks, the night shift was slightly more efficient than the day shift—1.5 percent and 0.7 percent respectively.) At the same time, the rate of absenteeism rose sharply from 2.2 percent at 40 hours to 9.7 percent at 43½. A partial explanation of this increase may be that a greater number of hours were involved in a day's absence during the 5-day, 43½-hour week than during the 6-day, 40-hour week. The slight rise in efficiency did not suffice to offset the sharp increase in absenteeism. As a consequence, the 8.8-percent increase in hours above 40 a week resulted in only 2.6 percent more output. In other words, only 1 hour of additional output was obtained for every 3½ hours added to the 40-hour schedule.

Turn-over.—As in the preceding day-shift study, most separations were due to "quits". The night-shift quit rate rose from 5.6 per 100 persons to 20.9 when hours were increased. This increase is similar to that of the day shift which had remained at the 6-day work schedule, while the night shift went on a 5-day week during longer hours. Dislike of work accounted for fully half of the quits at 44 hours.

Injuries.—Data combining disabling injuries and first-aid cases were available only for the period of a 44-hour, 5-day workweek. The weekly rate of injury cases per 1,000 workers was 23 for the night shift. On Monday, the injury rate was the same for both shifts and represented the lowest point of the week for the night shift. After Monday, it rose sharply and remained at a level above the peak of the day shift (on Thursday) for the remainder of the 5-day week.

Pay increases.—The night shift also received a bonus of 10 percent on total weekly earnings during the 40-hour week. As on the day shift, efficiency increased for the following 3 months—rising 6½ percent above the pre-bonus level—after which efficiency gradually declined.

When the rate for piecework units was increased—equivalent to an 11.9-percent raise—during the longer workweek, the night shift showed an increase in efficiency up to 6 percent during the following 5 months.

45: *Workweeks of 48 hours* vs. *40 and 45 hours, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves; women.*

The operation of machine-stripping tobacco leaves was identical with the one described in another cigar manufacturing plant, case study 43. The pace of work was fast and entirely controlled by the operator. There was no idle time. Work was light and continuous, demanding constant manual and visual attention. It was monotonous and repetitive, and required the rhythmic coordination of both hands and feet.

Working conditions.—There was only a moderate amount of dust in the selected department. The volume of noise also was moderate. Temperature and humidity were controlled and kept fairly high to keep tobacco in a proper condition for handling. Modern lighting and ample window space provided very good illumination. Music was played in the plant during various intervals of the day. Facilities for the comforts of workers generally were good.

The strong odor of tobacco and the warm and highly humid air occasionally caused headaches and nausea among workers. Exposure to industrial injuries was limited to minor cuts on fingers and hands. Work space and safety aisles were ample for the operation. The company had a good safety program and was well equipped to administer first aid.

Wage incentives.—Operators were paid under a piece-rate incentive system, and earned an average of 60 cents an hour.

Hourly schedules.—The performance of 13 selected women was followed from December 1943 to May 1946. During the selected period, the weekly and daily schedules worked were: (a) 48 hours (three 9½-hour days alternating with two 9¾-hour days); (b) 40 hours (five 8-hour days); and (c) 45 hours (five 9-hour days). One-half hour was allowed for lunch. Most of the selected female operators were of middle age and had 5 to 25 years' service with the company.

FINDINGS OF STUDY

The 9½- vs. *8-hour day.*—When daily hours were decreased from 9½ and 9¾ to 8 with retention of the 5-day week, efficiency rose steadily up to the end of the 40-hour period, at which point it had reached an increase of 19.3 percent. It is possible that efficiency might have leveled off at a point even higher than this. But at this point hours were increased.

The 16.7-percent reduction in hours, from 48 to 40 per week, had resulted in a loss of only 0.6 percent in average weekly output due to the sharp rise in efficiency. The 40-hour week therefore was practically as productive as the 48-hour week.

When daily hours were increased to 9 a day and a total of 45 a week, efficiency dropped 5.4 percent below the highest point reached at the end of the 40-hour period, though still remaining 12.9 percent above the efficiency level maintained during the 48-hour week.

The increase in weekly hours from 40 to 45 represented a 12.5-percent increase in hours and resulted in a 6.4-percent gain in output. The addition of 5 hours to the 40-hour week therefore resulted in approximately 2½ hours of additional output. In comparison with the 48-hour week, the 45-hour schedule represented a 6.2-percent drop in hours and a 5.8-percent gain in output. In other words, a gain of approximately 2¾ hours of output almost offset the 3 hours dropped from the 48-hour schedule.

The trend in absenteeism losses could not be related to changes in hours, as there were marked fluctuations in the monthly averages of absenteeism in all periods. The over-all level of absenteeism was 9 percent for the three levels of hours combined.

Turn-over.—A sharp drop in the number of separations was noted when hours were dropped, while accessions kept pace with separations. At 48 hours, the separation rate per 100 employees was 9.4; at 40 it was 4.4. When hours were again increased, to 45 per week, the separation rate remained almost unchanged (4.7) while the number of accessions rose to 8.7, indicating a period of expanded activities in which management made special efforts to keep its old employees. There were no discharges during the 45-hour week. The majority of separations were due to "quits for outside reasons" in all 3 periods. "Dislike of working conditions" was given for 12½ percent of the quits during 48 hours and for 8.7 percent during 40 hours, and 7.8 percent during 45 hours.

46: Workweeks of wartime 45 and 47 hours and postwar 40 hours, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves; women.

The operation of machine-stripping tobacco leaves in a cigar manufacturing plant was described in case study 43. Work was entirely operator-paced, light, rhythmic, monotonous, and repetitive. Coordination of both hands and feet was required in running the machine. Work was continuous and demanded constant visual attention. The pace of production was very fast in this shop.

Working conditions.—Humidity was kept high and temperature at a moderate level for proper handling of tobacco. Although ventilation was good, a strong odor of tobacco and ammonia pervaded the shop. Lighting was adequate and noise of medium volume. Facilities for the workers' comfort were strictly functional, restrooms often unattractive and even unsanitary. Smoking was forbidden in the plant.

Exposure to strong odors, the warmth, and the high humidity, resulted in frequent headaches and nausea. Work injuries consisted mainly of minor cuts on hands and fingers. First-aid facilities were adequate for the nonhazardous nature of this work.

Wage incentives.—Wages were paid at piece rates. As a measure of quality control, a ceiling was placed on earnings. Occasionally, an efficient operator reached her daily quota before the expiration of scheduled daily hours.

permitting her to go home early. As a rule, however, workers could not reach the ceiling on earnings without working a full day.

Hourly schedules.—The survey followed the performance of 24 women operating stripping machines. The period selected for study extended from October 1943 to March 1946. During the war, this period included a 45-hour workweek of 5 days at 9 hours per day, which was followed by a 47-hour week, and finally, by one of 46½ hours—with daily hours ranging from 9 to 9½. After the war, the performance during a 40-hour week could be studied, with daily hours reduced to 8. All schedule changes were obtained by changing daily hours without altering the pattern of a 5-day week.

FINDINGS OF STUDY

The 45-hour week vs. *47-hour week.*—When hours were increased from 45 to 47 per week, efficiency remained fairly constant, actually rising by an average of 0.7 percent, while the average percentage of time lost because of absenteeism dropped from 4.1 to 3.3. The slight improvement in performance resulted in an output rise of 6 percent as compared to an hourly increase of 4.4 percent. In other words, about 2¾ hours of additional output were obtained when 2 hours were added to the 45-hour week.

The subsequent 46½-hour workweek represented a period of a concerted drive by management to step up the production pace in an effort to offset the exodus of workers to more remunerative war industries at a time when replacements were difficult to obtain. This drive resulted in raising efficiency 3.1 percent above the level maintained during the preceding 47-hour week. The percentage of scheduled time lost due to absenteeism increased slightly, the absence rate rising from 3.3 percent to 4.6 percent. The combined effect of these two factors was to increase total weekly output fractionally (0.4 percent) although hours had been reduced by 1.1 percent. On the whole, the change of ½ hour in the weekly schedule had little effect.

The postwar 40-hour week.—The postwar reduction of the workweek to 40 hours resulted in a sharp and steady decline in efficiency during the first few months immediately after the war. When workers had settled down to normal peacetime production, the efficiency level had risen 1.1 percent above the level obtained during the preceding period of stepped-up production. Attendance also improved, the average rate of absenteeism dropping from the earlier level of 4.6 percent to 3.2 percent. The combined effect of improved efficiency and reduced absenteeism was reflected in a decline in total weekly output by only 11.7 percent as against a decrease in hours of 14 percent. Consequently, the elimination of 6½ hours from the 46½-hour week resulted in a loss of only 5½ hours of output.

47: *Workweeks of wartime 44½ and 46½ hours and postwar 40 hours, individual wage incentives; light, operator-paced operations in hand-stripping of tobacco leaves; women.*

The process of hand-stripping tobacco leaves is similar to that of machine-stripping (see case study 43). While seated at a knee-high work bench, the operator opens a wrinkled tobacco leaf, places it on the bench, holds the end of the tobacco leaf with one hand and, with a quick and even motion, tears the stem from the entire length of the leaf with the other hand. The cycle of the operation is completed when the two stripped halves of the leaf are stacked on the work bench.

Work was entirely operator-paced, light, rhythmic, monotonous and repetitive. The extreme boredom of the operation was enhanced by the lack of any machine noise and the minimum of conversation because of workers' preoccupation in their jobs. The work required dexterity of both hands and demanded continuous visual attention. The work pace was extremely fast.

Except for the absence of noise in hand-stripping, working conditions were the same as those described in case study 46.

The piece-rate incentive system was described in case study 46.

Hourly schedules.—The performance of 10 women, engaged in hand-stripping tobacco leaves, was followed from September 1943 to March 1946. During the entire period, only one shift was in operation, working 5 days per week.

Work schedules above 40 hours per week were obtained by adding ½ to 1½ hours to the 8-hour day while retaining the 5-day week. The 3 schedules observed were wartime workweeks of 44½ and 46½ hours, and a postwar week of 40 hours.

FINDINGS OF STUDY

The 44½-hour week vs. *46½ hours.*—The rise in the wartime schedule from 44½ hours a week to 46½ brought about a 4-percent drop in efficiency, while the rate of absenteeism remained at 2.8 percent in both periods. As a consequence, output increased only by 0.2 percent although hours had been increased by 4.5 percent. Thus, the 2 hours added to the 44½-hour week resulted in practically no increase in output.

When the labor shortage became acute and workers were leaving to go into better-paying war industries, management began a drive for more production to offset losses in personnel. Although weekly hours remained unchanged at 46½, workers' response to the production drive was reflected in a somewhat higher level of efficiency, the general level being 3 percent higher than in the preceding period of the same schedule of hours. Absenteeism losses remained almost unchanged, rising slightly from 2.8 percent to 3.1 percent. The campaign for more production succeeded in raising the output rate by 2.8 percent above the previous level for the same schedule. It succeeded in adding the output of 1⅓ hours to the weekly output total without an increase in working hours.

The postwar 40-hour week.—A postwar schedule of 40 hours per week was obtained by decreasing daily hours to 8. The immediate effect of this cut-back was a sharp rise in efficiency which reached a level 6.7 percent above that of the preceding 46½-hour week. Concurrently, absenteeism rose to 5.4 percent. Total output reflected the increase in the efficiency rate by declining less than hours. The 14-percent drop in the hours schedule was accompanied by a 10.5-percent decrease in output—a loss of a little more than 4¾ output hours for a reduction of 6½ scheduled hours from the 46½-hour week. Stated differently, the 6½ hours above the 40-hour level had resulted in 4¾ hours of output, and this during an intensive campaign for higher production.

48: Workweeks of wartime 44 and 46½ hours and postwar 40 hours, individual wage incentives; light, operator-paced operations in hand-stripping of tobacco leaves; women.

The process of stripping the stem from a tobacco leaf by hand was described in case study 47, which dealt with an identical operation done in another plant located in the same area. With the exception of the data cited below, the conditions enumerated in the preceding case study, 47, also apply to this case.

Temperature and humidity were more moderate in this department than in the one described in the preceding case study, as the only operation done in this plant was hand-stripping which does not require as high a degree of humidity as other cigar-making operations.

Hourly schedules.—The selected period extended from September 1943 to March 1946 and included weekly work schedules of 44 and 46½ hours during the war, and 40 hours after the war. The workweek consisted of 5 days for all periods. Changes in total weekly hours were obtained by changes in daily hours between 8 and 9½. A sample of 21 women, engaged in hand-stripping tobacco leaves, was selected for the survey.

FINDINGS OF STUDY

The 44-hour week vs. *46½ hours.*—The increase in the wartime schedule from 44 to 46½ hours per week resulted in a slightly poorer performance: efficiency decreased by almost 1 percent and absenteeism losses increased slightly, from the former rate of 2.5 percent to 2.9 percent. As a consequence, output did not increase in the same proportion as hours, rising only 4.2 percent while hours had increased by 5.7 percent. Expressed in terms of hours, 1.8 additional output hours were obtained by lengthening the 44-hour week by 2½ hours.

The drain on the wartime reservoir of available manpower, coupled with the exodus of workers from nonwar to war industries, induced management to step up individual production efforts. During this period, weekly hours remained unchanged from the preceding period—46½ hours per week. As a result of management's drive for more hourly output without increasing the work force or working hours, efficiency increased by almost 2 percent above the previous level for the same number of weekly hours. The decrease in the absence rate from 2.9 percent to 2.1 percent was negligible. The net effect of the production drive was a 2.7-percent rise in total weekly output, or a gain of 1½ output hours over the preceding period of the same weekly schedule of 46½ hours.

The postwar 40-hour week.—In the months immediately following the end of the war, the efficiency trend followed a sharp and continuous decline although the workweek had been reduced to 40 hours. After 4 months, however, the downward trend of efficiency was reversed and a continued rise of efficiency was in evidence up to the end of the selected period. Although efficiency may have increased still further during subsequent months at 40 hours, the last available measure of efficiency—2.7 percent above the preceding level of 46½ hours—represents at least the minimum of average performance to be expected for this level of hours. Absenteeism losses increased somewhat, rising from the previous rate of 2.1 percent to a level of 3.1 percent. Against a 14-percent decrease in hours (from 46½ to 40 hours a week) the output level decreased only 12.4 percent. Expressed in terms of hours, a loss of 5¾ output hours resulted from a 6½-hour reduction in the weekly schedule.

49: Workweeks of prewar 40 and 44 hours, wartime 46, 45, and 47½ hours, and postwar 40 hours, individual wage incentives; light, operator-paced operations in machine-stripping of tobacco leaves; women.

The process of stripping tobacco leaves by machine in a cigar-manufacturing plant was described in case study 43. General plant conditions were the same as those enumerated in case study 46, except for the differences cited below.

Hourly schedules.—The performance of 13 female operators of tobacco-stripping machines, selected for this survey, could be followed for a period extending from June 1941 to April 1946. The scope of the survey included, therefore, prewar as well as war and postwar periods of different work schedules. The standard workweek consisted of 5 days during the entire period surveyed. By increasing daily hours from 8 up to 9½, different levels of weekly hours were obtained.

FINDINGS OF STUDY

Prewar 40 and 44 hours.—Lengthening the 40-hour week by 4 hours prior to the war resulted in an efficiency drop of 3 percent. The percentage of scheduled time lost due to absenteeism was low for both periods, with absence rates of 1.9 percent and 0.8 percent for the 40- and 44-hour weeks respectively. Dut to the decrease in hourly output, the net gain in total weekly output was only 7.9 percent although hours had been increased by 10 percent. Slightly over 3 additional output hours were obtained by the addition of 4 hours to the 40-hour week.

Wartime 46 hours.—Although the first wartime schedule studied was 2 hours longer than the previous 44-hour week, hourly output increased sharply, by 13.8 percent, in spite of the fact that this plant was not engaged in war production. This increase must be attributed to a large degree to management's success in stepping up the pace of production to offset the labor shortage, which acutely affected nonwar industries. Absenteeism losses increased from 0.8 percent under the 44-hour week to 3.7 percent, indicating that the production drive was not as effective in keeping down absenteeism losses as it was in stimulating workers to greater efforts while at work. The increase in hourly output, however, was sufficient to step up output sharply by 15.6 percent while hours were increased by 4.5 percent over the preceding 44-hour week. Consequently, total weekly output was increased by 6¾ output hours with only 2 hours added to the schedule.

Wartime 45 hours.—The subsequent 45-hour period represented a 1-hour reduction from the previous 46-hour week. Efficiency increased by 5.8 percent during this slightly shorter schedule, primarily due to the continued pressure to increase output per man-hour. Absenteeism losses, however, continued to increase slightly, the rate averaging 5.1 percent. As a result of the increased efficiency, total weekly output actually increased by 2 percent while hours were decreased by 1 hour. Thus, the workers were producing almost one more hour of output for one hour less work per week.

Wartime 47½ hours.—During the final wartime schedule studied, weekly hours had been raised from 45 to 47½. Approximately the same level of hourly output was maintained as during the previous 45-hour week. Efficiency actually rose by almost 1 percent. Pressure for added output had apparently reached the point at which efficiency began to stabilize. The absenteeism losses dropped to 4.3 percent from the preceding level of 5.1 percent. The lengthening of the workweek from 45 to 47½ hours represented a 5.6-percent rise in hours as against a 7.2-percent increase in total weekly output, reflecting the combined effects of a slight increase in efficiency and a somewhat improved work attendance. In effect, the 47½-hour week represented a net gain of 3½ output hours for 2½ scheduled hours added to the 45-hour week.

Postwar 40 hours.—The months immediately following the end of the war were excluded from the study of the 40-hour postwar week as they represented an unsettled period of work performance. Although the workers were not engaged in war production, they had been under pressure to accelerate their production pace during the war. With the cessation of hostilities, a reaction set in as evidenced by a temporary slowing up of the work pace. Toward the end of the period observed, efficiency seemed to stabilize at a level about 1.3 percent higher than that obtained for the preceding 47½-hour week. Significantly, the postwar level of efficiency was 19.3 percent better than that experienced before the war for the same 40-hour workweek. The accelerated production pace, acquired during the war, had seemingly carried over into the postwar period.

Absenteeism losses were not reduced by the shortened postwar schedule, the level being 5.5 percent as compared with 4.3 percent for 47½ hours and 1.9 percent for the prewar 40-hour week. The slight increase of 1.3 percent in efficiency over the 47½-hour schedule was offset by the rise in scheduled time lost due to absenteeism, so that approximately 7½ output hours were lost when 7½ scheduled hours were eliminated from the 47½-hour week. Compared with the prewar 40-hour level, the postwar schedule of the same number of hours resulted in 15.1 percent more output each week, representing a gain of 6⅓ output hours over the prewar 40-hour week.

50: Workweeks of 40, 48, and 53 hours for women, individual wage incentives; light, operator-paced packing operations.

This study was conducted in a candle-manufacturing plant. The operation surveyed, hand-packing of candles, was light and required little special skill or training. The workers sat at long tables and placed a prescribed number of candles into market containers. The work pace was medium-fast, operator-controlled, and afforded very little idle time to the operators.

Working conditions.—Working conditions were good. The large work areas were free from dust, fumes, and noise. A modern ventilating system removed wax and acid odors: large windows and a complete fluorescent installation provided excellent light. Restroom facilities were sanitary and adequate. There were no eating facilities in the plant; employees brought lunches from home and ate at their work stations. Minor injuries were treated by an employee trained in first aid. There were no organized rest periods.

The work force.—Twenty-four female packers were selected for study. Their ages ranged from 25 to 65 years, with the largest concentration around 40 years. One-third of the work force had been in the company's employ for more than 10 years.

Wage incentives.—The workers operated under an individual bonus incentive system. They were guaranteed a minimum hourly base rate and received a premium for units produced in excess of a fixed quota.

Hourly schedules.—The period from April 1941 through December 1944 provided three levels of scheduled hours for study. During this period weekly hours changed from 40 (5 days at 8 hours) to 48 (5 days at 9 hours and a 3-hour Saturday) and subsequently to 53 (5 days at 9½ hours and a 5½-hour Saturday).

FINDINGS OF STUDY

Workweeks of 40 and 48 hours.—Efficiency was highest during the 40-hour week, with 5 days at 8 hours. When daily hours were increased from 8 to 9 and a 3-hour Saturday was added to the schedule, efficiency dropped 10.3 percent.

The percentage of time lost due to absenteeism almost doubled during the longer workweek. It increased from a level of 4.5 percent at 40 hours to 8.3 percent at 48 hours.

In terms of total output, the increase of 20 percent in scheduled hours resulted in an increase in output of only 3.3 percent. Thus, given the same hourly efficiency and absenteeism rate which prevailed during the shorter workweek, the additional output gained during the 48-hour week could have been obtained by increasing scheduled weekly hours from 40 to about 42.

Workweeks of 48 and 53 hours.—When weekly hours were raised from 48 to 53 by increasing daily hours to 9½ and lengthening the Saturday schedule to 5½ hours, efficiency rose slightly but was still 9.2 percent below the level which obtained during the 40-hour week.

The small improvement in efficiency, 1.3 percent, might indicate that the

Saturday schedule of 3 hours during the 48-hour week was too short. It is permissable to assume that the same amount of time was necessary to reach an operational level of efficiency during the 5½-hour as during the 3-hour Saturday. Consequently, the longer Saturday afforded an additional 2½ hours of production at the regular work pace.

Absenteeism was highest during the 53-hour week. The percentage of time lost due to absenteeism rose steadily from 4.5 percent at 40 hours to 8.3 percent at 48 hours, and to 9.4 percent at 53 hours.

The 10.4 percent increase in hours above 48 was accompanied by a 10.3 percent gain in total weekly output. The slight improvement in efficiency during the 53-hour week was offset by increased absenteeism with the result that about 5 hours of additional output were obtained for the 5 hours added to the 48-hour week.

Compared with the 40-hour week, the 53-hour week represented a 32.5-percent increase in hours. Total output, however, rose only 13.9 percent. Thus, although 13 hours were added to the schedule, only about 5½ hours of additional output were achieved.

51: Workweeks of 40 hours, 44½ hours, 53 hours, and 48 hours, group wage incentives; medium, operator-paced foundry operations; men.

This study was conducted in a small nonferrous metal foundry. The operations included those usually performed in a foundry—coremaking, squeezer and floor-mold casting, shake-out, and chipping. The work pace was steady and unhurried, and controlled by the operator. The physical demands of the work were medium. The castings ranged in weight from 20 to 200 pounds.

Working conditions.—Working conditions in this plant compared favorably with those observed in the average foundry. Unpleasant conditions, incidental to foundry operations, such as excessive heat, dust, and noise, existed in this plant only to a moderate degree. Dust collectors near sandblast machines were effective in reducing the dust content in the air. The high ceiling, with opening skylights, large window space on two walls and large openings in the third side of the building made for relatively comfortable temperatures and good ventilation. Noise was sufficiently low to permit music, played in the plant, to be audible in the foundry.

Aisles were wide and generally unobstructed. Work areas were clean and uncrowded. A complete fluorescent installation provided excellent lighting. Restroom and comfort facilities, including showers, were sanitary and adequate in number. Good, inexpensive lunches were served in the plant cafeteria.

Safety clothing and appliances were supplied by the company. Two nurses treated injuries in a well-equipped first-aid room.

Rest pauses, while not formally organized, were taken when the work flow permitted.

The work force.—The plant was located in a highly developed industrial area which provided an ample supply of stable, skilled, and experienced workers. As a result, when the foundry personnel was increased from 12 workers in 1940 to 56 in 1943, the effects on the quality of the labor force were insignificant.

The foundry workers were men whose average age was approximately 45 years. Of the original group of 12 workers, the majority were in the company's employ for more than 15 years. Management was of the opinion that the workers added to the labor force compared well with the old timers.

Wage incentives.—A group bonus system was in operation in the foundry. Workers were paid a guaranteed hourly rate and a premium based on the total foundry output. The hourly base pay rates amounted to $1.05 for coremakers and floor-mold operators and ranged from $.65 to $.85 for laborers.

Hourly schedules.—The periods selected for study permit comparison of four stabilized hourly levels. During the period from January through August 1940, the foundry operated on a 40-hour schedule of 5 days at 8 hours. The next period, extending from June through November 1941, was marked by the addition of 4.5 hours on Saturday, thus increasing the workweek to 44.5 hours. In June 1942, 6 months after our entry into the war, the workweek was increased to 53 hours with 5 days at 9 hours and Saturday at 8 hours. This schedule was maintained through November 1942. From January through May 1943, a reduced schedule of 48 hours, or 6 days at 8 hours, was worked.

FINDINGS OF STUDY

The 40-hour week vs. *44½ hours.*—When the level of hours was raised from 40 to 44.5 by adding Saturday at 4.5 hours to the workweek, efficiency dropped 1.9 percent.

Absenteeism increased from 1.2 percent to 4.2 percent.

Output increased to a level 5.9 percent above that which had prevailed during the shorter hours. This increase was effected by lengthening scheduled hours 11.3 percent. Stated differently, 2⅓ additional hours of production were obtained for the additional 4½ hours worked.

The 53-hour week.—The conversion to war production apparently acted as a strong stimulus to improved efficiency. When hours were increased from 44.5 to 53 per week, efficiency rose 5.3 percent.

The time lost because of absenteeism increased only slightly, from 4.2 percent to 5.5 percent.

The combined effects of a marked increase in efficiency and a small increase in absenteeism resulted in an output level appreciably higher than that of the prewar 44.5-hour schedule. Total output increased 23.6 percent during the wartime longer workweek. In comparison, hours had been lengthened 19 percent. In other words, an additional 10.6 hours of production were obtained when 8.5 hours were added to the schedule.

The 48-hour week.—After a period of 5 months on the 53-hour schedule, weekly hours were cut back to 48. The reduction in hours was accompanied by an increase in efficiency of 8.8 percent. The percentage of time lost, however, rose from 5.5 percent to 7 percent.

A decrease in scheduled hours of 9.4 percent resulted in a decrease in output of only 3 percent. In terms of hours, only 1.6 hours of output were lost when the workweek was reduced by 5 hours, from 53 to 48.

52: Intermittent schedules ranging from 24 to 48 hours a week for women, individual wage incentives; light, operator-paced machine-sewing operations.

The operations surveyed consisted of the various sewing operations entailed in the production of men's trousers. All operations were performed on electric-powered sewing machines and were entirely operator-paced. The pace was fast and the work required great manual dexterity. The speed and character of the operations were such that they induced a nervous rather than a physical strain.

Working conditions.—The plant facilities can be characterized as functional. No special effort was made to make the plant attractive or comfortable. The atmosphere was free from dust, smoke, or fumes. Summer and winter temperatures were moderate. Ventilation was good. The lighting installation, although not modern, provided adequate illumination. Noise was moderate. Aisles and work areas were usually unobstructed and were adequate in size. There was no cafeteria. There were no organized rest periods; pauses were taken when the work flow permitted.

The work force.—The plant was located in a small, rural, farming community. Most of the 96 female operators, whose performance was surveyed, had outside interests such as farming and gardening. During the planting and harvesting seasons, their tendency was to hold working hours down to an absolute minimum so as to allow them time for these outside activities. The workers ranged in age from 19 to 70 years, with a strong concentration in the late thirties. Most of them had high school education, were self-reliant, and skeptical of anything that smacked of company patronage.

Wage incentives.—All workers operated under an individual piecework system with a minimum guarantee of 40 cents per hour. The piece rates, based on company cost experience rather than time study, were set through negotiation between management and the labor organization representing the employees. Earnings ranged from 60 cents per hour to $1.25 and averaged about 80 cents for the entire group.

Hourly schedules.—During the entire 20-month period surveyed only one shift was scheduled. Hours nominally were from 7:45 a.m. to 4:45 p.m. including 1 hour for lunch. Actual hours worked by individual operators, however, varied greatly: while some worked as few as 24 or 30 hours per week, others—in other sewing operations—worked 48 hours. Schedules varied because of shortages of materials, the presence or absence of workers in key operations (such as pocket makers), and the pressures and delays involved in the carrying out of military contracts.

As a result, there were no fixed and uniform patterns of daily and weekly hours. Because of the fast pace of the work, however, it was believed that the effects of long weekly hours would be felt quickly—particularly so because the processes were of a routine, repetitive, mass-production character. The findings reflect the experiences of employees who worked a specified number of weekly hours at any time during the period surveyed. Thus, the output experiences of all operators who worked 48 hours, for example, were grouped together regardless of the particular month during which that schedule was worked.

FINDINGS OF STUDY

Efficiency.—Analysis of the experience of the 96 female operators indicates that the highest efficiency levels were obtained during a workweek of 24 or 28 hours. Thereafter the average hourly rate of output dropped as hours increased, although it remained fairly stable at the 32-, 36-, and 40-hour levels. Efficiency was lowest at 48 hours a week. A comparison of the efficiency level at 24 hours with that achieved during the 48-hour week shows an efficiency decline of 7.1 percent. In comparison with the 40-hour week, efficiency during the 48-hour workweek was about 4 percent poorer.

Absenteeism.—Because hours of individual workers varied widely, it was not possible to determine actual absenteeism rates measuring the percentage of scheduled hours lost. It was possible, however, to determine relative rates for each of the weekly schedules during which employees lost only part of a week and returned to work during the same week. (The computed rates understate the actual amount of absenteeism loss because of the exclusion of absences lasting an entire week.)

As hours increased from 24 to 40 a week, the relative absenteeism rate increased steadily, reaching a maximum of 6.3 percent during the 40-hour workweek. Thereafter absenteeism decreased sharply. At 44 hours it was 3.3 percent and at 48 hours, 1.2 percent. Apparently workers were anxious to earn the time-and-a-half bonus pay for overtime.

Output.—Generally, weekly output kept pace with increasing hours. As hours went up, weekly output went up proportionately. The higher efficiencies during the shorter workweeks, together with low absenteeism losses, resulted in an output situation averaging about 4.5 percent higher than that which obtained during the 40-hour week. When hours rose above 40, total output increased only about 2 percent more than did hours.

53: *Intermittent schedules ranging from 20 to 55 hours a week for men, individual wage incentives; medium-heavy, operator-paced pressing of men's trousers.*

The performance of 13 pressers was surveyed in the same plant which furnished the material for case study 52. Pressing, in this plant, was done by machine and foot-pedal-controlled hand irons and was entirely man-paced. The piecework incentive system and interdependence of all operations were conducive to a fast pace. Compared with other operations in the clothing industry, pressing appeared to be the most physically demanding.

Working conditions.—The atmosphere near the pressing machine was hot and often humid. Working conditions, otherwise, were similar to those described in the previous case study.

The work force.—Hourly earnings of the selected employees ranged from 85 cents to $1.30 and averaged $1.10. Most of the men owned and worked on small farms and vineyards. The supplementary income derived from this work served to make for a certain amount of independence in the workers' relations with the company. This manifested itself in several ways. It was almost impossible, for example, to schedule longer hours during the planting and harvesting seasons. The absence curve generally rose, according to management, during the hunting and fishing seasons. The introduction of new procedures often met with resistance on the part of workers who were skeptical of new-fangled ideas. In short, labor-management relations, while cordial, were marked by the particular influences found in a rural, farming community.

Hourly schedules.—There were no fixed and uniform schedules of daily and weekly hours. As was indicated in the previous study, hourly schedules were determined by the uneven work flow. Consequently, working hours frequently varied from week to week and differed among pressers during the same week. During the 20-month period surveyed the workweek for pressers ranged from 20 to 55 hours. The methods used to determine levels of efficiency and relative absenteeism rates during the various weekly schedules are the same as those described in case study 52.

FINDINGS OF STUDY

Efficiency was highest during a workweek of 24 or 28 hours. Thereafter hourly efficiency decreased as hours increased but remained fairly stable at 32, 36, and 40 hours. After 40 hours, however, efficiency dropped more sharply. The 55-hour week was about 6 percent poorer in average hourly output than the 40-hour week and about 9 percent poorer than the 24-hour week. It is also significant that hours below 24 per week were not as efficient as the longer hours and were on a par with the efficiency achieved during the 48-hour week.

Absenteeism.—There was no absenteeism during the 24-hour workweek. At 36 hours, it was 3.5 percent and at 40 hours it rose to 7.8 percent. But at 44 hours it was only 1.9 percent; at 48 hours, 0 percent; and at 55 hours, 1.2

percent. Apparently the incentive of overtime pay was responsible for the improvement in attendance during the longer workweeks. It is noteworthy that when hours fell below 24 per week, the percentage of time lost due to absenteeism rose to 4.4 percent.

Output.—Weekly output generally kept pace with increased hours, the decrease in absenteeism offsetting the decrease in efficiency. The output level was relatively as good at 44 and 48 hours as at 24 and 32 hours.

These conclusions are based on erratic hourly schedules. If the long hours had been worked steadily rather than intermittently, the value of overtime pay as an incentive to good attendance might have become less effective as fatigue accumulated. Furthermore, the downward trend in efficiency indicates that, had long hourly schedules been maintained for an appreciable length of time, the level of output would have been considerably lowered.

[1] Does not include full-week absences.

54: Intermittent schedules ranging from 28 to 52 hours a week for women, individual wage incentives; light, operator-paced sewing operations.

Machine- and hand-sewing operations were surveyed in a plant producing military and civilian overcoats during the war. The weight of the material handled ranged from 4 to 6 pounds. All work was performed under an individual piece-rate incentive system. The work pace was fast and controlled by the operator.

Working conditions.—The plant was located in a residential area of an industrial city and belonged to the same company which owned the rural plant described in case studies 52 and 53. Plant facilities were fair. Lighting and ventilation were poor. Work areas and aisles were often crowded and obstructed. There was no lunchroom. Comfort facilities met only minimum requirements. There was little dust, and noise was moderate. There were no organized rest periods.

The work force.—The performance of 32 experienced female operators was surveyed. Their ages ranged between 45 and 55 years. The great majority of them were married and had numerous home duties to perform outside of working hours. The average earnings of the group was about 90 cents per hour.

Hourly schedules.—As was indicated in the previous studies conducted in clothing plants, no fixed daily or weekly schedules were worked. While the nominal workday was 8 hours and the workweek 40 hours, this schedule was constantly revised depending upon the volume of work at hand and the work flow. As a result, schedules ranged from 28 to 52 hours a week during the 20-month period surveyed.

The methods used to compute levels of efficiency and relative absenteeism rates were the same as those described in case study 52.

FINDINGS OF STUDY

Efficiency.—An analysis of the performance of the selected group reveals a rise in efficiency of 6.3 percent as hours were increased from 28 to 40 a week. The improvement in efficiency as hours approached 40 a week indicates the added hours probably caused no fatigue and that actually the workers were able to utilize the added worktime to increase their earnings by increasing their hourly output.

The rising trend in efficiency, however, was reversed when the workweek extended beyond 40 hours. At 44 hours, efficiency dropped about 1 percent and at 52 hours about 3 percent from the efficiency level at 40 hours.

Absenteeism.—The percentage of time lost due to absenteeism remained fairly stable during the work schedules ranging between 28 and 40 hours a week. The relative percentages were 5 percent at 28 hours; 5.2 percent at 32 hours; 3.1 percent at 36 hours; and 4.8 percent at 40 hours.

As was true in case study 52, attendance improved when hours were increased beyond 40 a week. During the 44-hour workweek, the relative absenteeism rate was 2.3 percent. At 52 hours, it dropped to 0.6 percent. The increased attendance during the longer workweeks can be attributed to the workers' desire to remain on the job during those weeks when the extra—or overtime—hours were worked, in order to take advantage of the added overtime pay. The effect of a sustained period of long hours on absenteeism is not demonstrated in this study. It must be remembered that workweeks of 44 hours and more were scheduled only intermittently. It is likely, as previous studies have shown, that absenteeism would have increased had long hours been worked continuously for an extended period.

Output.—When weekly hours dropped from 40 to 28, the proportionate drop in total weekly output was 4 percent greater. At 36 hours, output kept pace with the change in hours. When hours were raised from 40 to 44, output increased by 2 percent more than did hours; at 48 hours output increased 1.9 percent more than did hours; and at 52 hours output increased 0.5 percent more than did hours. Thus, the drop in absenteeism offset the drop in effi-

ciency, but at a decreasing rate with each additional increase in hours above 40. The effects of fatigue are indicated, though perhaps to a lesser extent than would be the case if the schedules of long hours had been worked continuously rather than sporadically.

55: Intermittent schedules ranging from 28 to 52 hours a week for men, individual wage incentives; medium-heavy, operator-paced pressing of overcoats.

The performance of 22 hand- and machine- pressers was surveyed in the same plant which furnished the material for case study 54. A piece-rate system of payment was in effect. The work required long experience and was highly skilled. The physical effort required of the workers ranged from light to medium. With the exception of the higher temperatures near the pressing machines in this department, working conditions were similar to those described in the previous case study, 54. The nature of the operation made for a steady and deliberate rather than a fast pace.

The work force.—The men selected were urban workers whose average earnings were about $1.13 an hour. They ranged in age from 35 to as high as 71 years, with the highest concentration around 55 years. The selected group consisted of experienced workers who had spent from 15 to 50 years in the industry.

FINDINGS OF STUDY

Efficiency during irregular work schedules.—During the 20-month period surveyed, the workweek fluctuated between 28 and 52 hours. The methods used to compute efficiency levels and relative rates of absenteeism were the same as those described in case study 52.

A comparison of the performance of the selected workers during each schedule of hours reveals a steadily rising trend of efficiency as weekly hours were increased from 28 to 40. The level of efficiency during the 40-hour workweek was 4.7 percent higher than that of the 28-hour workweek and 4.1 percent higher than that of the 32-hour workweek. It would appear that when assured of a full week of work, the selected workers increased their hourly output.

When the workweek was increased beyond 40 hours, the upward trend in efficiency was arrested and hourly output leveled off. Efficiencies during the 44-, 48-, and 52-hour workweeks were approximately the same as that achieved during the 40-hour workweek.

The failure of efficiency to drop when hours were extended to 52 a week runs counter to the experiences noted in the previous clothing industry studies. In this connection, it should be recalled that (1) The work pace on this operation was deliberate rather than fast: (2) the workers were old-timers of a relatively high average age who had well-established ideas of what constituted a day's work: and (3) extended schedules of 44 hours and more per week were worked only sporadically rather than continuously.

Absenteeism.—Attendance remained generally stable during the entire 20-month survey period. The relative rates of absenteeism were 1.2 percent during the 28-hour workweek, 1.7 percent during the 40-hour workweek, and 1.2 percent during the 52-hour week. Once more, the comparatively low rates of absenteeism during long hours of work might be attributed to the workers' desire to earn the time-and-a-half pay for overtime. It is doubtful, however, in light of the experience observed in other industries, that the overtime pay would act as an incentive to good attendance, if long hours were worked continuously for an extended period rather than intermittently.

Output.—Output increased in almost exact proportion to the number of hours added to the schedules of 36 and more hours a week. When weekly hours dropped below 36, the approximate 4-percent drop in efficiency resulted in a comparable decrease in total output. The factors advanced earlier as possibly influencing the efficiency and attendance experiences of the group are also applicable in the analysis of its output experience.

[1] Does not include full-week absences.

56: Intermittent schedules ranging from 28 to 52 hours a week for women, individual wage incentives; light, operator-paced sewing operations.

This plant manufactured military and civilian jackets during the war. The work surveyed was about evenly divided between the operation of electric-powered sewing machines and hand sewing. As in case study 55, the operations in this plant required highly skilled and experienced workers. The production pace was importantly influenced by the strict quality control maintained by management. Although a piece-rate incentive system was in effect, the emphasis was on quality rather than on volume of output and made for a steady and unhurried work pace.

Working conditions.—Working conditions compared favorably with those described in the previous case study. Lighting and ventilation were good. Work areas and aisles were adequate in size and generally unobstructed. Noise was moderate. Comfort facilities were adequate. There was no cafeteria. Rest pauses were taken by individual workers when the work flow permitted.

The work force.—The performance of 123 female workers was surveyed for a period of 20 months. Most of the selected workers were between 45 and 55 years old and had worked from 5 to 25 years in the industry. They were characterized by management as experienced, stable workers who were dependent upon their jobs for their livelihood.

Hourly schedules.—This plant, like the clothing plants previously studied, could not maintain fixed daily and weekly schedules. The pressures of war contracts, the dislocations caused by material shortages, style changes, and the absence of key workers served to make the work schedules extremely flexible. Weekly hours ranged from 28 to 52 during the survey period. The methods used to compute levels of efficiency and relative rates of absenteeism were the same as those described in case study 52.

FINDINGS OF STUDY

Efficiency.—Analysis of the workers' performance indicates a small, gradual rise in efficiency as weekly hours were increased from 28 to 40. Hourly output during the 40-hour week was 2.8 percent higher than that achieved during the 28-hour week. When weekly hours were extended to 44, efficiency again rose slightly, less than 1 percent, and remained at that level during the 48- and 52-hour workweeks. Apparently, the workers, operating at a relatively slow pace, were able to maintain and even improve their hourly output during the intermittently scheduled longer workweeks.

Absenteeism.—The rates of time lost due to absenteeism reached their highest points, 6.8 percent at 32 hours and 6.1 percent at 40 hours. When weekly hours were lengthened beyond 40, the absenteeism rates declined sharply, dropping to 2.1 percent during the 44-hour week and 1.1 percent during the 52-hour week. The desire to earn the overtime bonus apparently acted as an incentive toward good attendance during the 44-hour and longer workweeks. But, again, the longer work schedules were worked only intermittently and the results achieved during these longer hours may not be indicative of what might have happened if they had been worked steadily over a long period of time.

Output.—Improved attendance and the relatively small increase in efficiency during the 44- to 52-hour workweeks resulted in a better total output situation than that which obtained during the shorter workweeks. While the 28-hour week represented a drop of 30 percent in hours from the 40-hour level, total output was 31.5 percent lower. During the 32-hour week, a 20-percent decrease in hours from the 40-hour level, total output was 23.4 percent lower. On the other hand, when hours rose 10 percent above the 40-hour level, output was 15.5 percent higher; when hours were increased by 30 percent (to 52) output increased 39.4 percent. The data indicate that the work pace was slow enough to permit the occasional scheduling of long workweeks without adversely affecting the performance of this group.

123 women on sewing operations

Item	Scheduled hours						
	28.0	32.0	36.0	40.0	44.0	48.0	52.0

[1] Does not include full-week absences.

57: Intermittent schedules ranging from 28 to 52 hours a week for men; individual wage incentives; medium-heavy, operator-paced pressing of jackets.

The performance of 29 male workers doing hand- and machine-pressing operations was surveyed in the same plant which furnished the material for the previous case study. The operations were entirely man-paced and, as a consequence of the strict quality control maintained by management, relatively slow. Working conditions were similar to those described in case study 56. Most of the selected men ranged in age between 45 and 60 years. They were a stable group of urban workers who had spent from 20 to 35 years in the industry.

FINDINGS OF STUDY

Efficiency.—Analysis of the workers' performance during workweeks ranging from 28 to 52 hours shows an experience similar to that noted for the female workers in the plant. As weekly hours were increased from 28 to 40, efficiency rose about 2.1 percent. When the workweek was extended to 44 hours, efficiency rose less than 1 percent above the level achieved during the 40-hour week, and remained at that level during the 48- and 52-hour workweeks.

Absenteeism.—The rates of time lost due to absenteeism, although significantly lower, followed the same trend observed in the absenteeism rates of female workers in the previous study. The rates were: 3.1 percent at 28 hours; 3.6 percent at 32 hours; 1.4 percent at 36 hours; and 3 percent at 40 hours. Thereafter absenteeism decreased sharply, dropping to less than 1 percent during the 44- to 52-hour workweeks.

Output.—As a result of the better attendance and the slight rise in efficiency, total output was somewhat better during the 44- to 52-hour workweeks than during the shorter weekly schedules. At 28 and 32 hours, the decrease in total output was slightly greater (1.4 percent) than the corresponding decreases in hours from the 40-hour workweek. When hours rose above 40, the increase in total output was 3.1 percent greater at 44 hours and 4.3 percent greater at 52 hours than the corresponding hourly increases above the 40-hour workweek.

In conclusion, it must be pointed out that previous studies have shown that the value of overtime pay as an incentive to good attendance deteriorates quickly when long hours are worked continually for an extended period. The uncommon experience of improved attendance during workweeks ranging from 44 to 52 hours, observed in all groups surveyed in the clothing industry, might be attributed to the intermittent scheduling of the longer workweeks. It is likely that the absenteeism and efficiency trends would have been quite different had the long hours been worked steadily.

Note: Examination of the efficiency trends of the six groups studied reveals a relationship between the work pace of each group and its trend of hourly output. In case studies 55 to 57, where the work pace was moderate or slow, the workers were able to maintain and in two cases slightly improve their hourly output as weekly hours rose to 52. On those operations where the work pace was fast, however (case studies 52 and 54), and in spite of the fluctuating nature of the schedule, increases in hours beyond 40 a week were accompanied by lowered efficiencies.

29 men on pressing of jackets

[1] Does not include full-week absences.

58: *Workweeks of 48, 40, 46, and 43 hours for women, individual wage incentives; light, operator-paced hat-finishing operations.*

This study was conducted in the custom trimming department of a men's hat-manufacturing plant. The operation surveyed was the hand-sewing of hat bands and trimming. The work pace was fast and controlled by the operator. Work was light and of a routine nature. Rest pauses were taken as the work flow permitted.

The workers operated under an individual piece-rate incentive system.

Working conditions.—The working conditions in this shop were excellent. Work areas were large and unobstructed. Lighting and ventilation were good. There was practically no noise. Music was played at frequent intervals during the day.

Plant facilities were very good. Inexpensive meals were served in a large, pleasant cafeteria. A motion picture projection room, ping-pong tables, and lounge chairs were provided for the employees' recreation. A large, fully equipped hospital sponsored by the company treated the illnesses and injuries sustained by employees. Many welfare services, such as a mutual benefit association, voluntary group life insurance, and a retirement pension plan, were available to the employee and her family.

The work force.—The performance of 28 women was surveyed for a period of 3 years. The labor force was characterized by management as stable and experienced. The ages of the workers were generally high, with the majority ranging from 45 to 55 years. Most of the workers had been with the company more than 10 years.

Hourly schedules.—During the selected period—August 1942 through July 1945—four different levels of hours were scheduled: (1) 48 hours per week with 6 days at 8 hours; (2) 40 hours per week by eliminating the 8-hour Saturday; (3) a 46-hour schedule, with 5 days at 8 hours and Saturday at 6 hours; (4) a workweek of 43 hours, consisting of 3 days at 9 hours and 2 at 8.

FINDINGS OF STUDY

48 vs. *40 hours.*—When the workweek was changed from 48 to 40 hours, by the elimination of Saturday, efficiency increased 3.7 percent.

The percentage of time lost due to absenteeism dropped from 10.7 percent to 8.4 percent.

The combined effect of increased efficiency and decreased absenteeism when scheduled hours were shortened by 16.7 percent resulted in a loss of 11.4 percent in total output. In other words, for the 8 hours dropped from the 48-hour schedule, only 5½ hours of output were lost.

40 vs. *46 hours.*—After the 40-hour week had been worked for 5 months, the workweek was increased to 46 hours by the addition of a 6-hour Saturday. Efficiency dropped 1.6 percent from the level achieved during the 40-hour week. It was, however, 2 percent higher than the efficiency level of the 48-hour workweek.

Absenteeism during the 46-hour week increased to a level of 10.3 percent, or comparable to the absenteeism rate of the 48-hour week.

Although hours were increased 15.7 percent above the 40-hour workweek, total output was increased only 10.7 percent. In terms of hours, for the 6 hours added to the schedule, 4½ hours of output were gained.

46 vs. *43 hours.*—After a period of 5 months, the workweek was reduced to 43 hours by eliminating Saturday and increasing 3 days of the week to 9 hours. Efficiency rose 2.9 percent above that of the preceding workweek of 46 hours. In comparison to the original 48-hour workweek, efficiency on this 5-day week was 5 percent higher.

Absenteeism increased from a level of 10.3 percent during the 46-hour week to 16.7 during the 43-hour week. The data do not reveal a specific reason for this increase in absenteeism. (The period during which the 43-hour schedule was worked, however, included VE-day and the vacation months of June and July. The increase in absenteeism might have been caused by unauthorized extensions of allowed vacation periods.)

The rise in absenteeism caused a loss in total output disproportionate to the decrease in scheduled hours. When weekly hours were reduced from 46 to 43 hours, or 6.5 percent, output dropped 10.7 percent.

In comparison to the original schedule of 48 hours, the difference of 10.4 percent in the scheduled hours was accompanied by a loss of 12.4 percent in output. Stated differently, 6 hours of output were lost when 5 hours were dropped from the schedule.

The workers apparently were more efficient on the 5-day schedules than on the 6-day schedules. In terms of over-all output, taking into account both efficiency and absenteeism, the most economical schedule appeared to have been the straight 40-hour workweek, with 5 days at 8 hours.

59: Workweeks of wartime 48 hours and postwar 40 hours for women, individual wage incentives; light, operator-paced operations in the packaging of biologicals.

The plant in which the department surveyed was located, was engaged in the manufacture of pharmaceuticals and biologicals. The departments included in case studies 60 through 63 were located in this same plant.

Operations in the selected department consisted of filling and capping or flame-sealing biological market containers. Mechanical filling machines and analytical balances were used. Each team of two operators was seated in a sterile, glass-enclosed room about 6 feet square. One worker filled the container, the other capped or flame-sealed it, and placed the container in a storage box. The work may be described as light, operator-paced machine operations.

Working conditions.—Working conditions were good. Lighting was excellent. Air conditioning kept temperature at 65 to 70 degrees, and dust was at an absolute minimum. Work was done under sterile conditions. The workers wore white caps, gowns, and masks over their mouths. Noise was at an absolute minimum. There were even restrictions against talking. The fragile glass ampules had to be handled with bare hands and there was a work hazard of accidental self-vaccinations from broken ampules. Resulting illnesses lasted from 3 to 6 days, but after several such self-vaccinations the workers usually developed an immunity, and no longer suffered ill effects.

Wage incentives.—Workers in the department operated under an individual wage-incentive system. In addition to a fixed hourly wage, the workers received bonuses for production in excess of established quotas.

Hourly schedules.—The performance of a selected group of 17 women on the day shift was surveyed under working schedules of 48 and 40 hours a week. The period of the 48-hour week, comprising 6 days of 8 hours, covered the last months of the war. After the war the workweek was shortened by eliminating Saturday work.

FINDINGS OF STUDY

Efficiency.—When the workweek was reduced from 48 to 40 hours, efficiency began to rise gradually, but steadily. The rising trend continued through the period available for study, and a stable level under the shorter workweek had not yet been reached by March 1946, the end-point of the period. At that time it had reached a point 12 percent higher than the level of efficiency which existed in the wartime period of the longer workweek.

Absenteeism.—Attendance was poor in both periods. Absenteeism averaged 12.1 percent during the wartime 6-day workweek, and rose after the war to 15.2 percent despite the elimination of Saturday work. This postwar trend in absenteeism appeared as well in case studies 60 through 63 which represent other groups of workers in this plant. It is possible that a wartime pressure for reduced absenteeism was removed after the war, and the resulting feeling of relaxation offset the decrease in weekly hours.

Output.—A stable level of weekly output under the shorter workweek schedule had not been reached by the end of the period as efficiency was still rising. By the last month of the period it had reached a point at which the 16.7 percent reduction in weekly hours meant a loss of only 10 percent in output. In terms of hours of output lost, the 8 hours eliminated from the schedule was accompanied by a loss of only about 4¾ hours of output each week.

Daily Pattern of Efficiency and Absenteeism

A combined analysis of daily patterns of efficiency and absenteeism under the two workweek schedules was made for all the selected workers represented in case studies 59 through 63.

Efficiency.—During the 48-hour workweek there was not much change in the level of efficiency for the different days of the week. The difference between the level for any one day and that for the other days of the week was never more than 2 percent.

When the sixth day was eliminated from the week, efficiency was higher on every day. The pattern showed a slight decline in efficiency on Tuesday, a subsequent rise through Thursday, the peak day, and a slight decrease on Friday. The range between the high and low points of the week, however, was narrow, not exceeding about 2 percent.

Absenteeism.—During the 6-day week, absenteeism declined from a high-point of 11.2 percent on Monday to 8.8 percent on Friday. It jumped sharply on Saturday, to 20.8 percent.

When Saturday work was eliminated, absenteeism was highest the first 3 days of the week, rising slightly from 10.7 percent on Monday to 12.7 percent on Wednesday. Thereafter it declined to 9.4 percent on Thursday, and 8.7 percent on Friday.

60: Workweeks of wartime 48 hours and postwar 40 hours for women, group wage incentives; light, operator-paced operations in the packaging of biologicals.

The women in this study worked on group incentives on the day shift in the same department as the group in case study 59.

Operations consisted of boxing and labeling biological and ampule products by hand. The women worked in groups seated along both sides of long tables. The items traveled on a conveyor belt in the center of the table. Equipment included glue-rolling, labeling, and taping machines. The work may be characterized as light, operator-paced packaging operations.

Working conditions were similar to those outlined in the preceding case study.

Wage incentives.—A group wage-incentive system was in operation. In addition to fixed hourly wages, the workers received bonuses based on excess production over fixed quotas for the group.

Hourly schedules.—The performance of 25 women was surveyed under a wartime workweek of 48 hours (6 days at 8 hours) and a postwar workweek of 40 hours (5 days at 8 hours).

FINDINGS OF STUDY

Efficiency.—During the 40-hour workweek period, efficiency showed a steadily rising trend to an end-point 6.9 percent higher than the level which had prevailed during the longer workweek schedule. A stabilized level had not been reached at the end of the period, and it is not known how much further efficiency might have risen.

Absenteeism.—Absenteeism remained essentially unchanged when the workweek was reduced to 5 days. The rates were high in both periods, 13.7 and 13.8 percent. The failure of absenteeism to decrease during the shorter workweek may have resulted from a possible easing-off of the wartime pressure for good attendance.

Output.—Although output had not reached a stabilized level at the end of the period surveyed, it had reached a point at which the 16.7-percent decrease in the workweek meant a drop of only 10.9 percent in output. At that point, only 5¼ hours of output were being lost each week for the 8 hours dropped from the schedule.

Daily Pattern of Efficiency and Absenteeism

A combined analysis of daily patterns of efficiency and absenteeism under the two work schedules for all selected workers in case studies 59 through 63 is presented in case study 59.

61: *Workweeks of wartime 48 hours and postwar 40 hours for women, individual wage incentives; light, operator-paced operations in the packaging of pharmaceuticals.*

The department surveyed was located in the same plant as that described in case studies 59 and 60.

Operations of these women consisted of bottling, labeling, and packaging dry pharmaceuticals for shipment. Boxes or bottles were filled by hand. A strip of cotton was placed in the top of each bottle, and the bottle was capped with a special hand tool. Labeling was done either by hand or by machine. The bottles were then wrapped in transparent paper, a descriptive folder enclosed, and the wrapping sealed.

Working conditions.—Lighting was adequate and noise, moderate. Large window areas and electric fans kept temperatures at a comfortable level. There was a moderate amount of dust. Aisles showed some amount of congestion and blocking.

Wage incentives.—An individual wage-incentive system was in operation. Workers received a fixed hourly wage plus a bonus based on production in excess of fixed quotas.

Hourly schedules.—The performance of a selected group of 26 women on the day shift was studied. During the war a 48-hour workweek was maintained, consisting of 6 days of 8 hours. After the war, Saturday work was eliminated, making for a 40-hour workweek.

FINDINGS OF STUDY

Efficiency.—When the workweek was reduced to 40 hours, efficiency began to rise, and continued to increase through the period surveyed. A stable level had not been reached by the end of the period, but efficiency had reached a point 5.1 percent higher than the level achieved during the earlier period of the 48-hour workweek.

Absenteeism.—Absenteeism was high under both schedules of hours with no appreciable difference in the rates: 9.4 percent during the wartime schedule of 6 days per week and 9.2 percent in the postwar period of the 5-day week. The continued high rate of absenteeism after the war, despite the cut-back in hours, as noted for the preceding groups surveyed (see case studies 59 and 60) may have resulted from a relaxation of the wartime pressures for good attendance.

Output.—Because of the steady rise in efficiency in the period of the shorter workweek, output had not yet reached a stabilized level. In the last month of the period, the 16.7 percent decrease in hours was accompanied by a 12.2 percent loss in output. At that point, 5¾ hours of output were being lost each week by the elimination of 8 hours from the schedule.

Daily Pattern of Efficiency and Absenteeism

A combined analysis of daily patterns of efficiency and absenteeism under the two levels of weekly hours for all selected workers in this plant is presented in case study 59.

62: Workweeks of wartime 48 hours and postwar 40 hours for women, group wage incentives; light, operator-paced operations in the packaging of pharmaceuticals.

The workers in this study were employed in the same department as those in case study 61.

The operations consisted of filling, capping, and labeling fluid pharmaceuticals. Bottles were cleaned by means of air jets and placed on a conveyor belt feeding a vacuum filling machine. Here the bottles were placed under filling nozzles, the nozzles lowered into the bottles, and the flow of liquid controlled by a foot pedal. The bottles were then capped and sealed by hand. The operations were performed while standing. They may be characterized as light, operator-paced, packaging operations.

Working conditions were the same as those cited in case study 61.

Wage incentives.—A group wage-incentive system was employed, whereby, in addition to an hourly wage, the workers received a bonus based on production in excess of fixed quotas achieved by the group.

Hourly schedules.—The performance of all workers in the group was surveyed under two levels of weekly hours. The number of workers ranged between 25 and 42. The working schedules were a wartime workweek of 48 hours (6 days at 8 hours) and a postwar workweek of 40 hours (5 days at 8 hours).

FINDINGS OF STUDY

Efficiency.—There was a slight increase of 1.5 percent in efficiency when hours were reduced from 48 to 40 per week.

Absenteeism.—The absenteeism rate was 6.4 percent during the 48-hour wartime workweek. It rose to 9.6 percent after the war despite the elimination of Saturday work, a possible result of an easing up after the pressures to maintain attendance during the war.

Output.—The 16.7-percent decrease in the workweek was accompanied by an 18.3-percent drop in output. The slight increase in efficiency was offset by the rise in absenteeism, with the result that 8¾ hours of output were lost by the elimination of 8 hours from the 48-hour workweek.

Daily Pattern of Efficiency and Absenteeism

A combined analysis of the daily patterns of efficiency and absenteeism under the two workweek schedules for all selected workers in the plant is presented in case study 59.

63: Workweeks of wartime 48 hours and postwar 40 hours for women, individual wage incentives; light, operator-paced operations in the packaging of cough drops.

The department surveyed was located in the same plant as the departments included in case studies 59 through 62.

The operations consisted of machine-wrapping and hand-packing cough drops. A roll of foil was hand-threaded through the wrapper machine. Cough drops were fed into the machine by a hopper, and were individually wrapped automatically. The operator hand-packed the wrapped cough drops in market containers, inserted a circular in the box, covered the box, and placed it on a conveyor. Although the wrapping machine was automatic, the operator was kept occupied in packing the cough drops, and her speed of operation was not limited by the speed of the machine. The work may be characterized as light, operator-paced, packaging operations.

Working conditions.—Excellent lighting was provided by fluorescent fixtures and white walls. The nature of the product required a controlled temperature of 75 degrees. There was a considerable amount of sugar dust in the air and on the floors. The floors were littered with cough drops and wrappers. The room was too small for the 14 machines installed in it. The noise of the machines was excessive and there was a high incidence of headaches. Unguarded moving parts of the machines extended into the aisles. According to the safety engineer, operators were inclined to insert fingers into moving parts of the machines to dislodge badly wrapped cough drops.

Wage incentives.—There was an individual wage incentive consisting of a bonus based on production in excess of a fixed quota in addition to the fixed hourly wage.

Hourly schedules.—This study surveys the performance of a selected group of 9 women on the day shift under two schedules of hours. During the war a 48-hour week of 6 days of 8 hours was worked. After the war Saturday work was eliminated, making for a 40-hour workweek.

FINDINGS OF STUDY

Efficiency.—The shortening of the workweek from 48 to 40 hours resulted in an increase of 7.9 percent in efficiency.

Absenteeism.—Absenteeism was high in both periods. During the 48-hour workweek the rate was 10.4 percent. It rose to 12.4 percent after the war in spite of the elimination of Saturday work. The trend is similar to that which occurred among the other groups of workers surveyed in this plant in the postwar period, and may have resulted from a possible relaxation in efforts to maintain good attendance.

Output.—The 16.7-percent reduction in the workweek resulted in a loss of 12.1 percent in weekly output. The elimination of 8 hours from the 48-hour workweek thus meant a loss of about 5¾ hours of output.

Injuries.—There was a sharp decline in the frequency rate of injuries in the department during the shorter workweek. In the wartime 48-hour workweek period, there was an average of 2,750 injuries (requiring first-aid treatment) per million man-hours of work among all workers in the department. After the war, when the workweek was cut back to 40 hours, the average decreased to about 1,400 injuries. The reduction of the workweek to 5 days thus reduced injuries by half.

64: Workweeks of prewar 40 and 55 hours, wartime 58 and 50 hours, postwar 45 to 50 hours for men, individual wage incentives; heavy, operator-paced machining operations.

Operator-paced machining processes on heavy metal parts were studied in this department. Work included grinding, single- and multi-spindle drill press, punch press, cold saw, assembling, sheet metal, arc, spot, and gas-welding operations. The work was heavy, and required a considerable amount of sustained physical effort. It entailed no idle operator time. The welding work imposed a nervous strain on operators. Continuous mental, visual, or manual attention was demanded on the majority of the operations.

Working conditions.—Within the limitations inherent in heavy metal-machining operations, care was taken to make the shop clean and safe. Lighting was adequate and noise of moderate volume. Some vibration, dust, and noise was caused by the punch-press operations. Soiled hands and clothing resulted from handling oily, greasy, and dirty materials. Heat and dampness were moderately high during the summer and rainy seasons respectively. Fumes and sparks were created by the welding operations.

The only food served in the plant was that offered by a mobile snack wagon which passed through every department twice each forenoon and afternoon coincident with the four 5-minute smoking periods, which constituted the organized rest periods installed in the plant. Workers were permitted to smoke in designated areas during these periods. Washroom and locker facilities were sanitary and adequate in number.

Safety.—Machines were safely spaced and well-guarded. The wide aisles had safety markings. A variety of lifting devices were used to reduce the frequency of injuries from improper lifting. Goggles and protective clothing were supplied wherever necessary. Conveyor belts under the floor automatically removed scrap metal. A safety engineer consulted with an active safety committee composed of management and employee representatives. The operators were to a considerable degree responsible for their own safety and that of their fellow workers; for example, guarding against possible eye injuries when blowing out metal chips with compressed air. Although welders wore special helmets and spark-proof clothing, they were exposed to burns or infections from sparks. There was a considerable amount of exposure to cuts, abrasions, crushed toes or fingers, and similar lost-time injuries. One physician and three nurses were employed full time, and another physician part time. Extensive facilities were available for the treatment of work injuries.

Wage incentives.—The selected workers were on individual wage incentives. Under the Dyer incentive system, time-study standards were set for 60 units of good work per hour as 100-percent efficiency to be expected from the average worker. Experienced operators were expected to earn at least 25 percent above the standard through incentive premiums.

Ten different labor grades were established with four pay-rate levels within each labor grade. Thus, the lowest grade included a range from 75 cents to 87 cents an hour, the highest grade from $1.38 to $1.58 an hour.

Overtime bonus during the war was paid at time and a half for all hours over 8 a day and over 40 a week. Before and after the war, it was paid at the rate of time-and-a-half for hours over 8 up to 10 a day, over 40 up to 50 a week, and for all work on Saturday. Double time was paid for daily hours over 10 and weekly hours over 50, and for Sundays and holidays. Incentive workers on temporary day work were paid their regular hourly rate plus 80 percent of the average incentive bonus during the preceding fiscal quarter.

Hourly schedules.—Company records did not indicate the number of hours worked each day or the number of days worked per week. It was, therefore, necessary to rely on company estimates for establishing daily breakdowns of weekly schedules worked.

The selected period extended from June 1940 to December 1945. It included the following weekly schedules and approximate patterns of daily hours: Before the war, 40 hours (5 days at 8 hours) and 55 hours (5 days at 10 hours, Saturday at 5); during the war, 58 and 50 hours (5 days at 10 hours, with additional Saturday work of 8 hours for a 58-hour week): after the war, 45 to 50 hours (5 days at 9 to 10 hours). The plant operated

2 shifts. The 18 male operators selected for this study were on the day shift, which started at 7 a.m. One-half hour was allowed for lunch when weekly hours were below 55, one hour when hours exceeded this level.

FINDINGS OF STUDY

It is pertinent to an analysis of the findings in this plant to note that workers became aware of the demand for the company's products in the war effort by the amount of increases in the available work load, in the size of the labor force, and in the length of the workweek. Management also exerted pressure for more production, for good attendance, and for improved safety conditions.

Prewar 40- and 55-hour weeks.—The prewar change in hours occurred when the 40-hour week was increased to 55 hours by lengthening daily hours to 10 and adding a 5-hour Saturday. During the longer workweek, efficiency declined by 6 percent.

Absenteeism losses remained unchanged, 2.7 percent at 40 hours and 2.6 percent at 55.

Total weekly output increased by 29.6 percent as against an increase of 37.5 percent in weekly hours, due to the decline in efficiency during the longer workweek. In terms of output hours, the addition of 15 hours to the 40-hour week increased total weekly output by the equivalent of 11.8 output hours.

Wartime 58-hour week.—The first wartime schedule studied was lengthened to 58 hours per week by increasing Saturday work from 5 hours to 8.

As cited in the introduction of the findings, workers were well aware of the need for the company's products in the war effort. As a result, their efficiency increased 11.9 percent above the hourly output level maintained during the prewar 55-hour week.

Absenteeism losses rose slightly, to 3.6 percent.

Total output increased by 16.7 percent over the preceding rate for 55 hours, although hours were raised by only 5.5 percent. In other words, the addition of 3 working hours to the prewar 55-hour week resulted in more than 9 additional output hours because of the higher level of wartime efficiency.

Wartime 50-hour week.—By eliminating the 8-hour Saturday, the next wartime schedule was reduced to five 10-hour days.

Efficiency increased by 7.4 percent over the preceding 58-hour week.

Absenteeism losses remained about the same, 3.6 percent for 58 hours and 3.4 percent for 50.

Output.—Because of the sharp rise in efficiency, output dropped only 7.1 percent as against a 13.8-percent reduction in hours—a loss of only 4 output hours for an 8-hour reduction in the weekly schedule.

Postwar 45- to 50-hour week.—The erratic postwar schedule ranged from 45 to 50 hours per week (five 9- to 10-hour days).

Compared with the prewar 40-hour week, postwar efficiency was 14.8 percent higher due to the accelerated production pace acquired during the war and carried over into the postwar period.

Absenteeism and output data could not be developed as the work schedule was very erratic and accurate information on absence rates was lacking for the postwar period.

65: Workweeks of wartime 58, 55, and 50 hours and postwar 48 hours for men, individual wage incentives; heavy, operator-paced machining operations.

The study follows the performance of 14 men on the day shift of the same department described in case study 64. Only points of difference from the preceding case study will be cited in this survey.

Hourly schedules.—As indicated in the preceding case, records revealed only total weekly hours, so that the number of hours worked per day, or days worked per week, were only approximations.

The selected period included wartime weeks of 58, 55, and 50 hours (5 days at 10 hours, with 5 or 8 hours on Saturday); and a postwar week of 48 hours (6 days at 8 hours).

FINDINGS OF STUDY

Wartime 58- and 55-hour weeks.—The wartime schedule of 58 hours per week was reduced to one of 55 hours by reducing Saturday work from 8 hours to 5, and retaining five 10-hour days.

Although some improvement in hourly output may be expected even for a 3-hour decrease from the schedule of 58 hours, the 15.1-percent rise in efficiency appears to be too drastic to be credited entirely to the slight reduction in hours.

Absenteeism losses remained relatively unchanged at 3.3 percent and 3.5 percent for the longer and shorter schedules respectively.

Total weekly output reflected the rise in efficiency by increasing 8.9 percent when weekly hours were reduced by 5.2 percent. Thus, the workers were producing about 5.2 more hours of output at 55 hours than at 58.

Wartime 50-hour week.—In the next war period, Saturday work was eliminated, leaving a week of five 10-hour days.

Efficiency rose 3 percent above the preceding 55-hour level.

The absenteeism rate of 3.3 percent was essentially the same as in the two preceding schedules.

The 9.1-percent decrease in hours from 55 to 50 per week brought about a drop of only 6.1 percent in total weekly output—a loss of 3 output hours as against a 5-hour reduction in scheduled hours.

Postwar 48-hour week.—The postwar 48-hour week was obtained by reducing daily hours from 10 to 8 and adding an 8-hour Saturday.

Efficiency increased 3.2 percent over the preceding 50-hour war period.

The absenteeism rate remained stable at 3.1 percent.

The 4-percent decline in hours was accompanied by a decrease of only 0.4 percent in total weekly output. In other words, the 2 hours eliminated from the previous 50-hour week resulted in practically no loss in output.

66: Workweeks of wartime 45 and 50 hours and postwar 45 hours for women, individual wage incentives; light, operator-paced manual and machining operations.

This study pertains to 9 women, on a day shift, engaged in manual bench and light machine operations involved in winding small coils. Work was light and repetitive, and the pace entirely operator-controlled. Continuous mental and visual attention was required.

Working conditions.—The work area was relatively quiet. Lighting and ventilation were adequate, as was the space available for work and safety aisles. Exposure to injuries was confined to minor cuts and bruises. In all other respects, working conditions were the same as those described in case study 64.

Hourly schedules.—As indicated in case study 64, the pattern of daily and weekly hours worked could only be approximated. When the workweek was raised from 45 to 50 hours during the war, the increase was obtained by lengthening the five 9-hour days to 10 hours each. After the war, the weekly schedule was again reduced to 45 hours.

FINDINGS OF STUDY

Wartime 45- and 50-hour weeks.—When the 5-day wartime week was lengthened from 9 to 10 hours a day, efficiency showed no apparent effect of the longer workday and actually increased by 1.2 percent.

Absenteeism losses also remained fairly stable at 5.3 percent during the 45-hour, and 5.8 percent during 50-hour schedules.

Total weekly output increased in almost direct proportion to the increase in hours, so that 5 hours added to the 45-hour week resulted in 5.3 hours of additional output.

Postwar 45-hour week.—When the postwar schedule was cut back to 45 hours by reducing daily hours from 10 to 9 for each of the five 10-hour days, the reduction in hours had no appreciable effect on efficiency, which improved by only 0.2 percent over the rate for the longer workweek.

Absenteeism losses, however, rose to 7.9 percent in the postwar period of shorter hours.

The 10-percent decrease in the schedule was accompanied by an 11.9-percent decline in total weekly output, so that the 5-hour reduction from the 50-hour week resulted in a loss of nearly 6 output hours. Compared with the wartime schedule of 45 hours, the identical postwar week showed a 1½-percent output loss equivalent to two-thirds of an hour's output. This difference, however, was attributable entirely to the increased absenteeism rate.

67: Workweeks of prewar 40 and 55 hours, wartime 62 and 55 hours, and postwar 40 to 48 hours for men, individual wage incentives; medium-heavy, operator-paced machining operations in a repair shop.

The performance of 14 male workers on the day shift of a repair shop was followed during prewar, war, and postwar work schedules. These workers were highly skilled and experienced. The process of machining returned company products and manufacturing service parts required the use of such machines as punch presses, drill presses, grinders, lathes, handscrew and milling machines, and hand and power tools.

With few exceptions, work was medium-heavy, highly skilled, and operator-paced. Workers were responsible for careful planning and fine workmanship to avoid costly scrap. As a result, the work pace was deliberate rather than fast.

Working conditions.—The machine-shop noise usual in this type of work was of medium volume, except around punch presses and hand screw machines where noise and vibrations were greater. Boring mills created some dust. The handled material was oily, greasy, and dirty. On some operations, hands, face, and clothes were spattered from lubricants. Temperatures were moderate, the shop was well ventilated and lighted. There was no crowding. The danger of work injuries was fairly high because of the variety of operations involved in this work.

Wage incentives.—Work in this repair shop was sufficiently standardized to permit the installation of an individual incentive system. Standards were established for major repair jobs. At least 75 percent of an operator's time was done on measured work.

For additional information on such factors as working conditions, safety, wage incentives, and hours, see case study 64 which dealt with another department of the same plant.

Hourly schedules.—As mentioned in case 64, the length of the workday and the number of days worked each week could only be approximated, as company records showed only total weekly hours worked.

The period selected for study included the following weekly schedules: Before the war, 40 hours (five 8-hour days) and 55 hours (five 10-hour days and a 5-hour Saturday); during the war, 62 hours (five 11-hour days and a 7-hour Saturday) and 55 hours (as above); after the war, 40 to 48 hours (five to six 8-hour days).

FINDINGS OF STUDY

An analysis of the findings must include a consideration of the type of operator and work involved. As already mentioned, the operators were highly skilled. Work was greatly diversified. Close tolerances and exacting workmanship as well as careful planning was necessary to avoid costly scrap.

As a consequence, the work pace was deliberate rather than fast and could be readily maintained, or even stepped up, when the backlog of work—and with it scheduled hours—increased.

Prewar 40- and 55-hour weeks.—For a period prior to the war, a 5-day week of 40 hours was compared with a 55-hour week of 5 days at 10 hours and Saturday at 5.

Lengthening of the week was accompanied by a 5.6-percent increase in hourly efficiency.

The amount of scheduled time lost due to absenteeism was small during all hourly schedules, the rate rising from 1.8 percent at 40 hours to 2.9 percent at 55.

The gain of 43.6 percent in output when weekly hours were increased by 37.5 percent must be attributed to the rise in efficiency. Expressed in terms of hours, 17½ more output hours were obtained through the addition of 15 hours to the 40-hour schedule.

Wartime 62-hour week.—During the war, the weekly schedule was further increased to 62 hours by changing daily hours from 10 to 11 for 5 days and from 5 to 7 for Saturday.

Despite this additional increase in hours, efficiency increased 3 percent above the previous level at 55 hours.

Absenteeism losses remained low at 2.6 percent.

Total weekly output increased by 16.6 percent when the former 55-hour week was increased by 12.7 percent, again due to improved efficiency. Consequently, a gain of 9 output hours was obtained when 7 hours were added to the 55-hour week.

Wartime 55-hour week.—During a later war period, hours were cut back to the former 55-hour schedule (five 10-hour days and one 5-hour day).

The reduced workweek was 2.1 percent more efficient than the preceding schedule of 62 hours.

Absenteeism losses at 55 hours (1 percent) were almost negligible.

The combined effect of improved efficiency and lower absenteeism losses resulted in an output decrease of only 8 percent as against an 11.3-percent reduction in hours—a loss of only 5 output hours when 7 hours were eliminated from the former 62-hour schedule. Compared with the prewar 55-hour week, the wartime schedule of the same hours resulted in 7.2 percent more output, or an additional 4 output hours.

Postwar 40- to 48-hour week.—After the war, the workweek fluctuated between 5 and 6 days at 8 hours, for total weekly hours of 40 to 48. Efficiency dropped almost 1 percent below the last war period of 55 hours, due perhaps to less pressure for more production and a resultant slackening of the work pace. The faster pace developed during the war, however, was not entirely dissipated during the postwar period, as indicated by a 10-percent higher level of efficiency than that which had characterized the prewar 40-hour week.

68: *Workweeks of prewar 36, 43, and 54 hours, and wartime 60 and 52 hours for men, individual wage incentives; medium-heavy, semi-automatic operations.*

Most operations performed by the 10 day-shift men surveyed in this study were done on engine and turret lathes, with some work on borematics, internal, and surface grinders. Work was diversified and exacting, usually requiring close tolerances. Most operations involved a predominance of machine time during which the operator watched, checked, and adjusted the work. A high degree of skill and judgment was demanded of the operator to prevent costly scrap. The production pace, therefore, was deliberate and fairly uniform rather than fast. Work was semi-automatic and medium-heavy. The operators had only a limited control over the speed of operations.

Working conditions.—The usual machine-shop noises prevailed in this department. Some of the disagreeable features of the work were the dirt of parts handled, grinding sludge, mica dust, grease, and spray from coolants. Ventilation and lighting were adequate. The work areas were spacious and the safety aisles wide and unobstructed.

For additional information on plant conditions, see case study 64, which deals with another department of the same shop.

Hourly schedules.—Company data on work schedules were limited to total weekly hours, so that the break-down of the number of hours per day and the number of days per week worked during each schedule could only be approximated.

The period selected for study included a prewar period of 36 hours a week, consisting of 4½ days at 8 hours; a 43-hour week of 5 days at 8 to 9 hours; and a 54-hour week of five 10-hour days, and a 4-hour Saturday. A 60-hour week of five 11-hour days and a 5-hour Saturday, and a 52-hour week of 5 days at 10 to 11 hours, were studied during the war period.

FINDINGS OF STUDY

In general, this study demonstrates that semi-automatic precision work —with the emphasis on quality rather than speed of production—resulted in a deliberate and fairly stable work pace readily maintained by the operator regardless of the length of working hours.

Prewar 36- and 43-hour weeks.—Prior to the war, a change in weekly hours from 36 (four and one-half 8-hour days) to 43 (five 8- to 9-hour days) was accompanied by a 4.7-percent drop in efficiency.

In the light of subsequent schedule changes which brought about only small changes in hourly output, the 4.7-percent decrease in efficiency is not readily explainable.

There were almost no absenteeism losses at 36 hours (0.2 percent) while the 43-hour week showed a rate of 4.8 percent.

As a result of a 19.4-percent rise in hours, output increased 8.6 percent —the difference being due to the combination of lowered efficiency and increased absenteeism. By adding 7 hours to the 36-hour week, only 3 additional output hours were obtained.

The prewar 54-hour week.—The next prewar schedule, of 54 hours per week, was achieved by working five 10-hour days and adding a 4-hour Saturday.

Compared with the preceding 43-hour week, efficiency rose by 3.2 percent.

Absenteeism losses dropped from 4.8 percent to 3.3 percent.

Total weekly output was increased by 31.7 percent as against a 25.6-percent rise in hours. The equivalent of 13½ output hours was obtained by the addition of 11 hours to the 43-hour week.

Wartime 60-hour week.—During the next schedule, a wartime 60-hour week, one hour was added to each day of the week for a workweek of five 11-hour days and a 5-hour Saturday.

Efficiency remained almost unchanged, the average being 0.7 percent higher than that during the preceding 54-hour period.

Absenteeism dropped slightly, to 2.3 percent.

The lower absenteeism losses together with the slight rise in hourly output, effected a gain of 13.1 percent in total weekly output as against an 11.1-percent increase in hours. This meant a gain of 7 output hours for an addition of 6 hours to the preceding 54-hour week.

Wartime 52-hour week.—During the last period studied, wartime hours were reduced to 52 a week by eliminating Saturday work, leaving the work schedule at 5 days of 10 to 11 hours each.

During the shortened wartime schedule, efficiency rose 2.3 percent above the previous 60-hour week, reaching a level of hourly output actually 1.3 percent above that maintained during the prewar base period of 36 hours.

The amount of scheduled time lost due to absenteeism rose slightly, to 3.9 percent.

A comparison of the two war periods of 60 and 52 hours indicated that a 13.3-percent reduction in hours resulted in a 12.9-percent loss in total weekly output. The elimination of 8 scheduled hours resulted in nearly the same reduction (7¾ hours) of output. Compared with the prewar base period of 36 hours per week, the wartime week of 52 hours represented an hourly increase of 44.4 percent and an output gain of 41 percent—an addition of 16 scheduled hours for a gain of 14¾ output hours.

Analysis of Injuries for Case Studies 64 to 68

A study was made of the frequency of all disabling and nondisabling injuries occurring at the different hourly levels in the prewar, war, and postwar period. A plant-wide sample of 36 high-seniority and 31 low-seniority workers was selected for this study, representing the departments surveyed in case studies 64 to 68. The group of workers who had been with the company before the war (high-seniority workers) represented a heavy age concentration around 45 to 50 years. The other group of low-seniority workers hired since the beginning of the war were in the 30- to 45-year age groups. The total number of injuries reported for each group was identical, 328.

High-Seniority Workers

A prewar change from 40 hours per week to 52 and 55 brought about a slight increase in the frequency rate of injuries per million man-hours of exposure from 863 to 910. This count consisted primarily of minor injuries requiring only first aid. In spite of the long workweek maintained during the war, the frequency rates were considerably lower than those before the war: 666 for workweeks from 57 to 60 hours, and 685 for weeks from 50 to 53 hours. Possibly, the reduction in the number of injuries was the result of increased stress on safety during the war in an effort to keep up production by saving man-hours. During postwar hours from 44 to 48 a week, the rate dropped to 475—a reflection of the combined effects of shorter hours and, possibly, improved safety conditions and practices.

Low-Seniority Workers

The newer workers, hired during the war, showed the opposite relationship between changes in hours and injury frequency rates. As hours went down, the frequency rate of injuries went up. During the wartime week of 57 to 60 hours, the frequency rate per million man-hours was 1,722 injuries (mostly first-aid), which rose to 1,803 for a weekly schedule of 50 to 53 hours toward the end of the war. For the postwar week of 44 to 48 hours, the rate was 2,163. The reason for this unexpected experience was not apparent.

Injuries by Hour of the Day[4]

An injury distribution by hour of the day was available for 167 cases requiring first-aid treatment during an 8-hour day and for 429 cases during a 10-hour day. The totals represent the experiences of 100 workers during a 17-month period, under either schedule. The workday began at 7 a.m., and lunch time was at 12 noon, under either schedule.

During the 8-hour day, the lowest percentage of the total number of injuries of the day occurred in the first hour of the morning—1.8 percent. After the first hour, the percentage increased sharply until it reached a forenoon peak of 16.8 percent during the fourth hour. The fifth hour, being the last hour before lunch, showed a slight drop to 12 percent.

The first afternoon hour (or sixth hour of the workday) had almost the same percentage of total injuries as the last forenoon-hour—11.4 percent. In the seventh hour the percentage reached a level equal to the forenoon peak; in the eighth and last hour, the high point of the day was reached—25 percent. The last figure may have been exaggerated if workers held off until the end of the workday before visiting the first-aid room for treatment of injuries incurred earlier in the day.

During the 10-hour day, the first morning hour again contained the smallest number of injuries—5.4 percent of all injuries for the day. As in the case of the 8-hour day, the percentage increased hour after hour until it again reached the forenoon peak in the fourth hour, 14.1 percent, with the fifth hour, the hour directly before lunch, again showing a slight drop, to 11.7 percent.

---

[4] See table 16, page 41.

The benefit of a lunch-time rest apparently contributed to the drop to 7.2 percent in the first afternoon hour. Thereafter, the percentage increased steadily until it reached the afternoon peak of 13.3 percent in the fourth afternoon hour, the ninth hour of the day. The last hour of the day again showed a slight recession and represented 11 percent of the total number of injuries during the entire 10-hour day.

69: Workweeks of 40 and 48 hours, in prewar, war, and postwar periods, for men, day shift, individual wage incentives; medium-heavy, operator-paced press-molding operations in the manufacture of rubber products.

This plant produced a variety of rubber products. The department selected for study was engaged in the manufacture of molded rubber specialties such as washers, force cups, bottle covers, etc.

Operations of the selected group of 21 workers on the day shift consisted of press-molding rubber stock. Each worker operated a battery of presses. Stock was placed in molds which, when full, weighed between 15 and 60 pounds, the average being about 45 pounds. The molds were lifted by hand into the press, and, after processing, lifted off and unloaded with the aid of an air hoist. Very little idle time was afforded the operator. While one press was in operation, he was occupied with the loading or unloading on the other presses in the battery. The work may be characterized as medium-heavy, operator-paced, press-molding of rubber products.

Working conditions.—Working conditions were fairly good. Adequate lighting was furnished by overhead reflector fixtures, large window areas, and skylights. Noise was moderate. Ventilation was adequate, but was not successful in removing strong rubber odors. The temperature was generally moderate, but was hot in the immediate vicinity of the molding presses in the summer, the temperature sometimes reaching 140 degrees. Aisles were wide and generally unobstructed. In some areas liquid rubber drippings and dust from soapstone and talc (used in rubber processing) made floors slippery. Danger signs were prominently displayed in these areas.

The company conducted an active safety campaign. Two safety engineers worked in conjunction with departmental safety committees. Safety equipment was furnished where required. A first-aid room was staffed with a doctor and four nurses.

There were no formal rest periods. A paid lunch period ranged from 12 to 20 minutes for men, and 30 minutes for women.

Wage incentives.—An individual wage-incentive system was maintained. Earnings were based on the percentage of a fixed production quota actually achieved by each worker.

The maintenance of standards was complicated in the rubber industry during the war by the substitution of synthetic for natural rubber. This prevented study of most rubber manufacturing operations. In this department, however, the change in the type of rubber stock did not affect standards, and the findings were comparable in all periods.

Hourly schedules.—The first period studied occurred several months before the war. A 40-hour workweek composed of 5 days of 8 hours prevailed. In response to a need for increased production, a sixth 8-hour day was added, making for a total of 48 hours a week. This schedule was maintained for the remaining months before the war and through the period of war production studied. After VJ-day, the workweek was cut back to 40 hours by eliminating the sixth workday. The day shift worked from 8 to 4, and from Monday through Friday or Saturday, depending on the length of the workweek.

FINDINGS OF STUDY

The findings illustrate the effect of increased work loads and conversion to war production, and the extent to which such factors influence the effects of changes in work schedules. The six case studies which follow represent different groups of workers in the same plant. Analysis of their performance shows a general similarity of experience.

Prewar Experience

The efficiency level of this group of workers increased 3.5 percent when the workweek was lengthened from 40 to 48 hours. Apparently the longer workweek was not particularly fatiguing to the workers. Moreover, it would appear that the work pace prevailing under peacetime conditions required less than maximum effort, and the workers were able to raise the level of hourly output when confronted with an increased work load. It should be noted, however, that workers could increase their output only by shortening the periods necessary to load and unload their machines.

Absenteeism was very low during the period of the 40-hour workweek, and rose only slightly under the longer hours. The rate in the first period was 0.7 percent. It increased to 1.7 percent in the later period.

The increase in total weekly output kept pace with that of hours. Increasing scheduled hours by 20 percent effected a rise of 22.8 percent in output, a gain of about 9 hours of output for the 8 hours added to the workweek.

War Experience

During the war period, at a continued schedule of 48 hours, efficiency rose 17 percent above that for the same 48-hour schedule before the war, bringing the level to a point 21.1 percent above that of the original 40-hour workweek period. To the stimulus of an increased work load was now added one of war morale, with the knowledge that production was directly connected with the war effort.

Absenteeism rose during the period to an average of 2.3 percent. This, however, was still low.

Because of the higher efficiency during the war, output increased 16.3 percent over the level achieved during the 48-hour workweek before the war. This resulted in an increase of the equivalent of 7¾ hours of output per week.

Compared to the normal prewar 40-hour workweek, the 20-percent increase in the schedule was accompanied by a 42.8-percent rise in output. Thus the workers were producing 17 additional hours of output for the 8 hours added to the workweek.

Postwar Experience

After the war, when the 40-hour workweek was restored, efficiency dropped 4 percent from the wartime level. The workers apparently eased up somewhat in their work pace when the pressure of production for war was removed, and the work load lightened. However, the postwar level of efficiency was still 16.3 percent better than under the prewar schedule of identical hours.

Injuries

An analysis was made of the combined injury experience of the 61 workers in the department represented in case studies 69 through 73.

In the prewar period of the 40-hour workweek, there was an average of 444 first-aid cases per million man-hours of work. When the workweek was extended to 48 hours by adding a sixth workday, the average rate was increased to 596.

In the war period studied, the longer workweek was maintained, and in some cases further increased to 54 hours. However the rate of first-aid cases dropped to 242 per million-man hours, a decline of about 50 percent. This drop apparently reflected the effectiveness of an intensified safety campaign to keep losses of manpower due to injuries down to a minimum during the crucial war period.

The improvement in the frequency rate of first-aid cases was carried over into the postwar period. Hours at this time were reduced from 48 to 40 per week. The rate remained at about the same level as in the preceding period. The average was 247 first-aid cases per million man-hours of work.

70: *Workweeks of 40 and 48 hours in prewar, war, and postwar periods, for men, evening shift, individual wage incentives; medium-heavy, operator-paced press-molding operations in the manufacture of rubber products.*

The 8 men selected for this study were on the evening shift in the same department and on the same operations as the workers in case study 69.

Working conditions, wage incentives, and workweek schedules were identical for both groups. Working hours were from 4 p.m. to midnight, and the workweek extended from Monday through Friday, or Saturday, depending on the length of the workweek.

Prewar Experience

The workweek was lengthened from 40 to 48 hours by adding a sixth day of 8 hours, several months before the war, to meet requirements for increased production.

Efficiency rose 1.6 percent under the longer workweek schedule. The work pace apparently was originally sufficiently slow to allow the workers to accelerate the pace without increased fatigue in response to the demands for more output. A similar trend in efficiency was observed for the day-shift workers during this period.

Absenteeism was low under both workweek schedules. The rates were 1.1 and 1.4 percent in the two periods respectively.

Output kept pace with the change in hours. The 20-percent increase in the schedule resulted in a rise of 21.4 percent in output, a gain of about 8½ output hours for the 8 hours added to the schedule.

War Experience

With a continued work schedule of 48 hours per week, efficiency during the war rose 21.1 percent over the prewar 48-hour level, a net gain over the original 40-hour workweek level, of 23 percent. All-out production for war may have stimulated the workers to greater effort. Again the trend is similar to that among the day-shift workers, but the rise in efficiency was more pronounced in the evening shift.

Absenteeism rose to 3 percent in this period.

Output during the 48-hour war week increased 19.3 percent over that of the prewar 48-hour workweek, a result of the higher efficiency. This furnished an additional 9⅓ hours of output per week. The 20-percent increase in the hourly schedule over the prewar 40-hour workweek was accompanied by a gain of 44.8 percent in weekly output, adding 18 output hours per week for the 8 hours added to the schedule.

Postwar Experience

With the end of the war, the decrease in the work load, and the restoration of the 40-hour workweek, efficiency dropped 4.1 percent. It would appear that the work pace was slowed down with the removal of the wartime pressure for greater output. The experience of the men on the day shift was similar in this period. Despite the postwar decline in hourly output, the new efficiency level was still 18 percent higher than it had been under the same work schedule before the war.

71: Workweeks of 40 and 48 hours in prewar, war, and postwar periods, for men, night shift, individual wage incentives; medium-heavy, operator-paced press-molding operations in the manufacture of rubber products.

This study presents an analysis of the performance of 10 men on the night shift in the same department, and on the same operations as the workers in case studies 69 and 70.

Working conditions, wage incentives, and workweek schedules were the same as those outlined in case study 69. The workday comprised the hours from midnight to 8 a.m. The 6-day workweek began on Sunday night and extended through Friday night. The 5-day week began Monday night and extended through Friday night.

FINDINGS OF STUDY

Prewar Experience

Efficiency increased 1.9 percent when the workweek was lengthened from 40 to 48 hours. As was indicated for the workers on the earlier shifts, a slow work pace in the initial period, enabled the workers to maintain and even better their rate of hourly output when an increase in production necessitated longer weekly hours. The rate of increase, however, was not as great as that achieved by the men on the day shift.

Absenteeism increased from 1.7 to 2.8 percent when the sixth workday was added. The rate of absenteeism was somewhat higher than for the day- and evening-shift workers, but the percentage was not considerable.

The 20-percent increase in the workweek was accompanied by a proportionate increase of 20.8 percent in output. The addition of 8 hours each week thus resulted in 8⅓ additional hours of output.

War Experience

The 48-hour workweek was maintained during the war period surveyed. Efficiency rose 26.7 percent over the level of the prewar week of 48 hours, and was 29 percent above the level of the original 40-hour workweek. As previously stated, production at this time was directly connected with the war effort, and knowledge of this fact may have spurred the workers to accelerate their work pace. The rate of increase was greater among the night-shift workers than among the day- and evening-shift workers discussed in case studies 69 and 70.

Absenteeism rose to 4.1 percent during the war period. Again the rate was higher than among the workers on the other shifts.

With no change in weekly hours, there was an increase of 24.9 percent in total weekly output as a result of the sharp rise in efficiency. This served to add 12 hours of output each week. The 20-percent increase in hours over the prewar 40-hour workweek was accompanied by a net gain of 50.8 percent in output. Thus the addition of 8 hours to the workweek resulted in a gain of 20 hours of output.

Postwar Experience

When the workweek was restored to 40 hours with the end of the war and the return to peacetime production, efficiency decreased 8.9 percent from the wartime level. The drop was greater than that experienced by the men on the earlier shifts. Despite the decline, however, efficiency was still 17.6 percent better than under the same schedule of hours before the war.

72: *Workweeks of 40, 48, and 54 hours in prewar, war, and postwar periods, for men, day shift, individual wage incentives; medium-heavy, operator-paced operations in the manufacture of rubber products.*

The 13 men selected for study worked on the day shift in the same department as the men on press-molding operations in case study 69. They performed a variety of operations in the manufacture of molded rubber specialties. These operations included machine-buffing rubber products; machine-cutting rubber stock into desired lengths; cutting spiral strips of rubber on a lathe; and table work, consisting of assembly of miscellaneous articles incidental to the preparations of the stock for processing. The work may be characterized as medium-heavy, operator-paced.

Working conditions and wage incentives were identical with those in case study 69.

Hourly schedules.—A normal 40-hour workweek of 5 days of 8 hours was increased to 48 hours by adding a sixth 8-hour day several months before the war. The weekly schedule was further increased to 54 hours during the war period surveyed by increasing daily hours from 8 to 9. The 40-hour week was restored at the end of the war.

FINDINGS OF STUDY

Prewar Experience

Efficiency showed a slight improvement of 0.8 percent during the period of the 48-hour workweek which followed the normal 40-hour workweek schedule. The possibility of an original slow, steady work pace that enabled the workers to maintain their level of efficiency under the lengthened workweek, which was noted for the press-molders in the department, existed for these workers as well.

When the workweek was extended from 40 to 48 hours absenteeism increased slightly, from 1 to 1.7 percent. The rates were low in both periods, and the percentages were similar to those of the press-molders on the day shift in the same periods.

Output rose in proportion to the increase in the workweek. The 20 percent increase in hours was accompanied by a 20.2 percent rise in output. The 8 hours added to the schedule thus resulted in an additional 8 hours of output each week.

War Experience

During the war, when the workweek was further increased by increasing daily hours from 8 to 9, efficiency rose an additional 9.6 percent, a net increase in efficiency over the original prewar level of 10.5 percent. The possible effect of conversion to war production on efficiency, as illustrated in case studies 69 through 72, for other male workers in the department is pointed up by the finding for this group. However, the rate of increase in hourly output was less in this instance. It may be significant that the workweek was extended to 54 hours during the war for these workers, while the other groups continued to work a schedule of 48 hours a week.

Absenteeism rose to 2.3 percent during the period. Again the rate is similar to that of pressmen on the day shift.

The 12.5 percent increase in weekly hours resulted in a rise of 22.7 percent in output. In effect, almost 11 output hours were gained by adding 6 hours to the workweek.

The 35-percent increase in hours over the prewar 40-hour workweek was accompanied by a net increase of 47.5 percent in output. The 14 hours added to the workweek therefore resulted in 19 additional hours of output.

Postwar Experience

When the workweek was restored to 40 hours after the war, efficiency rose 2.7 percent. This is in contrast to the decrease in efficiency among the other groups of men in the department during the postwar period. The difference may be attributed to the fact that there was a sharper decrease in the workweek in this case, from 54 to 40 hours. Efficiency in the postwar period was 13.5 percent better than under the same schedule of weekly hours before the war.

73: Workweeks of 40 and 48 hours in prewar, war, and postwar periods, for women, day shift, individual wage incentives; light, operator-paced trimming and finishing operations in the manufacture of rubber products.

The 9 women selected for study were engaged in hand- and machine-trimming and finishing operations in the same department as the men in case studies 69 through 72.

There was a variety of operations. Among them were hand trimming, in which the operator trimmed and finished the molded rubber articles with shears or knives; machine-trimming, in which the articles were placed on spindles and guided against knives; buffing; and machine-punch, or hydraulic-machine trimming, in which stock was trimmed by means of machine-operated dies.

Working conditions and wage incentives were the same as outlined for men in case study 69.

Hourly schedules.—An orginial 40-hour workweek of 5 days of 8 hours was lengthened to 48 hours several months before the war by the addition of a sixth 8-hour day. The 48-hour week was maintained during the war period surveyed. In the postwar period, intermittent workweeks of 40 to 48 hours were scheduled, depending on production needs.

FINDINGS OF STUDY

Prewar Experience

The increase in the workweek from 40 to 48 hours was accompanied by a 1.2 percent increase in efficiency. An orginal steady work pace, requiring less than maximum effort is suggested by the trend, which is similar to that for male workers in the department during the period.

Absenteeism rose from 2 to 4.7 percent with the addition of Saturday work. The rates were higher than for men on the day shift under the same work schedules.

The increase in output did not quite keep pace with that of hours, because the increase in absenteeism more than offset the increase in efficiency. The 20-percent increase in the workweek was accompanied by a 17.9-percent increase in output. The addition of 8 hours to the workweek therefore netted 7 hours of additional output.

War Experience

During the war period surveyed, under a continued schedule of a 48-hour workweek, there was a further improvement in efficiency of 6 percent. The aggregate increase in efficiency over the level which obtained during the prewar 40-hour workweek period was 7.3 percent. While the trend is similar to that among the male workers during this period of production for war, the degree of increase was not nearly as sharp.

Absenteeism jumped to 9.2 percent during the war period. The sharp rise may indicate the possibility of an accumulaton of fatigue over an extended period of a 48-hour workweek for women, many of whom undoubtedly had additional duties at home.

Output increased by only 1.2 percent over the preceding level, with no change in the workweek, the increase in absenteeism serving to offset the increase in efficiency. About two-thirds of an hour of output was gained each week during the period.

The 20-percent increase in hours over the 40-hour workweek was accompanied by a net rise of 19.3 percent in output. In terms of hours of output, the 8 additional scheduled hours per week resulted in a gain of nearly 8 hours of output.

Postwar Experience

Under an intermittent schedule of 40 to 48 hours a week after the war, efficiency was maintained at nearly the same level as that achieved during the war. The change was a slight decrease of 0.3 percent. Compared with the period of the 40-hour workweek before the war, there was a net gain of 6.9 percent in efficiency in the postwar period.

74: Workweeks of 40, 48, and 57 hours in prewar, war, and postwar periods, for men, day shift, individual wage incentives; light to medium-heavy, operator-paced operations in the manufacture of rubber tubing.

This department, in which the selected group of 14 men worked on the day shift, was located in the same plant as the department surveyed in case studies 69 through 73.

Operations in the department were connected with the manufacture of rubber hose. Rubber stock was extruded through a tubing machine in lengths of 50 feet or less, and passed over a mandrel. A cloth jacket was then wrapped tightly around the hose, and the hose vulcanized. After vulcanization, the cloth jacket was removed, the hose stripped off the mandrel, and the ends of the hose trimmed and finished. The work may be characterized as light to medium-heavy and operator-paced.

Working conditions.—Working conditions were good. Lighting was adequate, noise was moderate, and temperatures were comfortable. Flooring was wooden and was somewhat slippery in spots from soapstone dust. Ventilation was adequate. There was considerable talc dust in the air, however, which management insisted no ventilating system could eliminate.

Wage incentives.—Earnings were based on an individual incentive system which operated in the same fashion as that outlined in case study 69.

Hourly schedules.—The workweek was increased from 40 to 48 hours several months before the war to meet demands for increased production. This was effected by adding a sixth 8-hour day to the original workweek of 5 days of 8 hours. During the war period surveyed the workweek was extended to 57 hours by an increase in daily hours from 8 to 9½. After the war, the workweek was cut back to 48 hours.

FINDINGS OF STUDY

Prewar Experience

When the workweek was increased from 40 to 48 hours, efficiency rose 3.9 percent. The observation is suggested that, as in the case of the workers in case study 72, the original work pace of these workers was not the best of which they were capable. Consequently they were able to accelerate their pace, and thus improve efficiency, when confronted with a need for greater output, despite the lengthening of the workweek.

Absenteeism rose from 3 to 4.6 percent when the sixth workday was added.

The 20-percent increase in the workweek resulted in a rise of 22.8 percent in output. In effect, the 8 hours added to the schedule resulted in a gain of a little better than 9 hours of output each week.

War Experience

Efficiency increased an additional 12.7 percent during the war period surveyed, under a workweek schedule of 57 hours, bringing it to a point 17.1 percent above the level achieved during the prewar period of 40 hours. The rise may be attributed to a possible acceleration of pace under the pressure of all-out production for war. A similar trend was noted for the workers in the other departments surveyed in this plant (see case studies 69 through 73) but the extent of the increase was not as sharp as it had been for the men in the previous studies whose weekly hours were increased to only 48.

Absenteeism decreased from the preceding level of 4.6 percent. The rate during the war period was 2.9 percent. No explanation was found for this decrease.

The 18.8 percent increase in hours from the 48-hour schedule resulted in a rise of 36.1 percent in output. For the 9 hours added to the workweek, output equivalent to 17⅓ additional hours was obtained. Compared to the original 40-hour workweek, the 42.5-percent increase in the schedule was accompanied by a rise of 67.2 percent in output, a gain of 27 output hours for the 17 hours added to the workweek.

Postwar Experience

When hours were reduced from 57 to 48 a week as a result of a decrease in production demands after the war, efficiency showed a further increase of 1.3 percent.

Compared to the original prewar period of the 40-hour workweek, efficiency was 14.1 percent higher in the postwar, 48-hour week.

75: Absenteeism during 58-hour workweeks of 5 and 6 days in a plant manufacturing aircraft; plant-wide bonus; men and women.

This survey included all machining and assembling operations involved in the production of airplanes. In general, the work pace was medium-fast and steady, and controlled by the operator. All operations were light.

Working conditions.—The buildings were new and working conditions in the plant were excellent. High ceilings, outside walls consisting almost entirely of windows, and complete installations of fluorescent lights assured excellent lighting and ventilation. Dust, fumes, and noise were kept at a minimum. Work areas were extensive, allowing for wide aisles and plenty of working space. Housekeeping was exceptionally good. Two cafeterias and two restaurants provided meals for the employees. Carts with hot food traveled through the plant. There was a 10-minute rest period, paid for by the company, on each shift.

The most modern safety conditions existed in the plant. Aisles and intersections were clearly marked, machines well-guarded. By means of committees, workers in each department were kept alert to the observance of all possible safety precautions.

The work force.—Approximately 7,000 men and 3,000 women worked in the plant. About 75 percent of the operations did not require any previous experience. The labor force, drawn largely from cities and towns within a 40-mile radius of the plant, ranged widely in age—from 18 to 61 years. According to management, men and women of different nationalities and races worked together harmoniously, on both the day and night shifts.

Wage incentives.—A plant-wide bonus incentive system based on the number of completed planes produced each month was in operation in the plant. Examination of the bonus data revealed that changes in design, materials, and methods, rather than the efforts of the workers, were largely responsible for the variations in the percentages of average monthly bonus earnings. While the change in scheduled hours undoubtedly affected workers' efficiency, it was impossible to isolate the effects of this change from those of the other changes mentioned. Consequently it was not possible to measure the effect of changes in scheduled hours. Findings are restricted entirely to absenteeism.

FINDINGS OF STUDY

An analysis of plant-wide absenteeism percentages was made for the period from March through December 1943. Although the workweek remained at 58 hours throughout the entire period, the daily schedule was changed from 5 days at 11.6 hours to 5 days at 10 hours, with Saturday at 8 hours. The effect of this change on the percentage of time lost due to absence was insignificant. The level of absenteeism for men changed from 6 percent during the 5-day week to 6.2 percent during the 6-day week, and absenteeism among female workers dropped from 9.6 to 8.8 percent. Absenteeism was generally higher for women than for men during both schedules.

Although there was very little difference in the weekly absenteeism rates during both schedules, examination of the daily patterns reveals that from Monday through Friday absenteeism during the 6-day week was lower than during the 5-day week. Saturday absence, however, on the 6-day schedule, was the highest of the week and served to dissipate the improvement noted during the rest of the week.

The best attendance of the week occurred on Thursday, which was pay day. The desire for a long week end probably accounted for the highest absenteeism rates on Monday and Saturday. For the other days of the week, the rates were relatively level.

76: Comparison of absenteeism by sex and shift; light, operator-paced machining and assembling operations; no wage incentives.

The absenteeism experience of men and women was studied on three shifts of one plant and on two shifts in another plant. Both plants were located in the same area and belonged to the same company. Operations consisted of machining and assembling small steel and brass parts, weighing less than 5 pounds, for carbines, rifles, and fuses.

Most of the work could be characterized as light and man-paced. It was done at a steady and moderate pace.

Working conditions in both plants were good. Temperatures were moderate, ventilation was good, lighting modern and adequate. There was little noise or dust. Ample space was allowed for the work area and for safety aisles. Safety conditions were excellent. Protective clothing was provided for wherever needed, machines were well-guarded, and safety rules were strictly enforced. First-aid facilities were very good.

The work force in both plants was almost equally divided between men and women. Of the 745 men, 404 worked on the day shift, 237 on the afternoon shift, and 104 on the night shift. Of the 704 women, 436 worked on the day shift, 196 on the afternoon shift, and 72 on the night shift.

The average age of the men was 40 to 45 years, and of the women, 35 years. As the wartime labor market was very tight in the area, help was inexperienced and had to be trained on the job, with many women operating machines formerly considered as men's jobs. A number of women of advanced age (up to 70 years old) were placed on light work that could be performed in a sitting position.

Wage incentives.—Workers were paid at straight hourly rates ranging from 60 cents an hour for unskilled labor to $1.50 an hour for the highest skilled operators. The afternoon shift received a 5-percent shift bonus, the night shift 10 percent. In the absence of wage incentives, no individual performance records were available for a possible study of efficiency.

Hourly schedules.—Wartime hours covered in this study included 48, 50, and 55 a week for an average workweek of six 8-hour days with an occasional seventh day at 8 hours. Starting times for the day, afternoon, and night shifts, respectively, were 8 a.m., 4 p.m., and 12 midnight. The company paid for a 20-minute lunch period.

FINDINGS OF STUDY

The highest percentage of absenteeism was recorded on the night shift for both men and women—7.1 percent for men and 11.9 percent for women. A somewhat lower absence rate was found on the afternoon shift for both sexes in both plants—6.2 percent and 5.8 percent for the men, 9.5 percent and 9.4 percent for women. The lowest rate of absenteeism was registered on the day shift in both plants—5.5 percent and 4.9 percent for men, 8.5 percent and 8.1 percent for women.

The amount of scheduled time lost due to absenteeism was lower for men than for women on each of the three shifts.

The rate of absenteeism increased more sharply for women than for men with each later shift. In one plant, female absence rates exceeded those for men on the day shift by 3 percent, by 3.3 percent on the afternoon shift, and by 4.8 percent on the night shift. In the other plant, female absence rates exceeded those for men by 3.2 percent on the day shift and 3.6 percent on the afternoon shift.

77: Daily patterns of absenteeism for men and women during 5- and 6-day workweeks, individual wage incentives.

The plant studied manufactured regulators, armatures, and generators. With the added work load during the war, plant conditions became increasingly congested and controls over accurate reporting of individual production data became progressively lax. As a result, individual efficiencies did not seem to bear any relationship to hours during weekly schedule changes from 40 to as high as 67 hours, nor was it possible to correct efficiencies in order to obtain true performance data. It was deemed necessary, therefore, to limit the study to a comparison of daily absences on a 5-day and a 6-day week for men and women. The 10 men selected for the study of wartime absenteeism belonged to the day shift of the final assembly department. They were engaged in assembling generators with the aid of hand or power-driven tools while standing at a long bench. Work was medium-heavy and man-paced. Working conditions were poor—aisles were obstructed and work areas congested. Lighting was inadequate. Safety conditions were poor because of crowding; machines were inadequately guarded and safety regulations were poorly observed.

The 22 women selected for study belonged to the day shift of the armature department. Work was performed with the women seated at a bench and included such manual operations as coil-winding, soldering, finish-turning, and testing. The work was light and operator-paced, requiring manual dexterity. General working conditions were good and the work area was less congested than elsewhere in the plant.

One-half hour was allowed for lunch.

FINDINGS OF STUDY

For the men, a 40-hour week of five 8-hour days was compared with a 59½-hour week of five 10-hour days and a 9½-hour Saturday.

For the women, a 40-hour week of five 8-hour days was compared with a 48-hour week of six 8-hour days.

The absenteeism rate was higher for each day of the week during the 6-day week worked by both men and women, with Saturday showing a very sharp increase in the rate.

Daily absences during the 5-day week ranged from less than 1 percent to approximately 2 percent for both sexes.

During the 6-day week, male absences ranged between approximately 2 percent and 4 percent for 5 days and rose to 17½ percent on Saturday.

Female absences during the longer workweek ranged between approximately 3½ percent and 4 percent for the first 5 days and increased to 20½ percent on Saturday.

78: *Wartime workweek of 48 hours* vs. *postwar workweek of 35 hours, individual wage incentives; light, machine-paced machining operations; men and women.*

This plant was engaged in the manufacture of piston rings for airplane and automobile motors.

Operations in the department studied consisted of machine-grinding rough castings. The castings were processed through a series of grinding machines which progressively shaped them into the specified forms and sizes. The work was of a semi-automatic nature, allowing the operator only a limited amount of control over the pace. The work entailed only moderate physical exertion, but constant visual and mental attention. The work may be characterized as light, machine-paced machining operations.

Working conditions.—Working conditions were good. Excellent light was furnished by a complete fluorescent lighting system. Good ventilation was provided by a large amount of window area, and an extensive fume removal system. Grinding wheels were enclosed to keep dust and flying particles to a minimum. Noise was kept to a level moderate enough to permit frequently piped-in music to be audible. Wide aisles and adequate work areas were kept clean and generally unobstructed.

Safety.—A full-time safety engineer conducted an active campaign with the assistance of a plant safety committee. Machines were well-guarded, and safety clothing and appliances were supplied where necessary. A modern first-aid room was operated by a registered nurse.

The work force.—The findings are for all the operators and helpers in the department during the period of survey. All operators were males, and all helpers, females. No figures were available as to the proportion of men to women. In the earlier months of the study there were about 50 workers in the department. In the later months this figure was reduced to 30, as a result of a postwar decline in the work load and a consequent lay-off of personnel. Despite the change in the number of workers represented, it is believed that the findings in the two periods studied were comparable. The personnel remaining in the last period were all experienced workers who had been in the department in the earlier months. Thus the experience of 30 of the 50 workers is included in the findings in both periods.

Wage incentives.—A group wage-incentive system was in operation during the period studied. Under this system the aggregate excess production over time-studied standards was computed for the week for the entire department and each worker received, in addition to his base pay, a bonus of 1 percent of his pay for each 1 percent of production above standard.

Hourly schedules.—During the war period studied, the workweek consisted of 6 days of 8 hours, for a workweek of 48 hours. At the end of the war, faced with a cut-back in production, the company undertook several economy measures. These included a program of reduction in the labor force and a shortening of the workweek to 35 hours by eliminating Saturday work and decreasing daily hours from 8 to 7.

FINDINGS OF STUDY

Efficiency declined 3.6 percent from the level achieved during the war under the 48-hour workweek schedule. This may be attributed to a general feeling of uneasiness and insecurity induced by the falling off of available work and the lay-offs, which could cause a lowering of morale and a stretching of the work to make it last longer.

Absenteeism.—Attendance improved only slightly under the shorter workweek schedule. The rate of absenteeism during the wartime period of the 6-day workweek was 5.7 percent. When the sixth day was eliminated and the workday reduced from 8 to 7 hours, the level of absenteeism dropped to 4.1 percent.

Output.—The net effect of the 27.1 percent decrease in the workweek from 48 to 35 hours was a loss of 28.6 percent in total weekly output. In terms of hours, the 13 hours dropped from the weekly schedule resulted in a loss of 13¾ hours of output.

Injuries.—A comparison of the frequency of all injuries requiring first-aid treatment under the 48-hour workweek schedule of the war period, and a postwar schedule of 40 hours a week, which replaced the 35-hour workweek several months after the war, reveals that under the longer weekly hours work injuries (nearly all requiring only first aid) occurred at the average rate of 5,839 per million employee-hours of work. During the shorter workweek of 40 hours, this figure was reduced to an average of 3,852 injuries per million employee-hours. The decline in the rate is a measure of the effect of the elimination of Saturday from the workweek.

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., June 4, 1947.

The Secretary of Labor:

I have the honor to transmit herewith a report on work stoppages caused by abor-management disputes in the United States during 1946.

This report was prepared by Don Q. Crowther and the staff of the Labor-Management Disputes Division, under the general supervision of Nelson M. Bortz, n the Bureau's Industrial Relations Branch, Boris Stern, Chief.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Work Stoppages Caused by Labor-Management Disputes in 1946

Summary

The 4,985 work stoppages arising out of labor-management con- oversies in 1946 exceeded the previous year's total of 4,750; the umber was also slightly greater than the former peak in 1944, when ,956 stoppages were recorded by the Bureau of Labor Statistics. pproximately 4.6 million workers were directly involved in the stop- ages which began in 1946—a larger number than in any previous year n record. Idleness at the plants or establishments directly affected y stoppages aggregated 116 million man-days, or triple the time lost 1945 (38 million man-days). The average duration of a strike in 946 was approximately 24 calendar days, or about four times as long s during the war period.

Wages were a major issue in most controversies. Protection of orkers' "take-home" pay was emphasized in many of the earlier econversion wage disputes, but later in the year, after the easing and ubsequent abandonment of price controls, demands for pay increases o match rising living costs became more frequent.[1]

Thirty-one large work stoppages, involving 10,000 or more workers ach, began in 1946. They affected 2,925,000 workers, or about two- hirds of the total involved during the year. Including the 6 stoppages f 10,000 or more workers which began in late 1945 and continued into he early months of 1946, idleness resulting from these large stoppages ccounted for nearly 82 million of the 116 million man-days of idleness eported for all work stoppages during the year.

The time lost from stoppages in 1946 amounted to 1.4 percent of he estimated working time of that portion of the country's labor orce which might have become engaged in labor conflicts. Total roduction in 1946, as measured by the Federal Reserve Board's index, limbed to successive record peacetime levels during the year. Em-

---

[1] For a more detailed analysis of the issues involved in stoppages during the year after VJ-day, see Postwar ork Stoppages Caused by Labor-Management Disputes, in Monthly Labor Review, December 1946 p. 872).

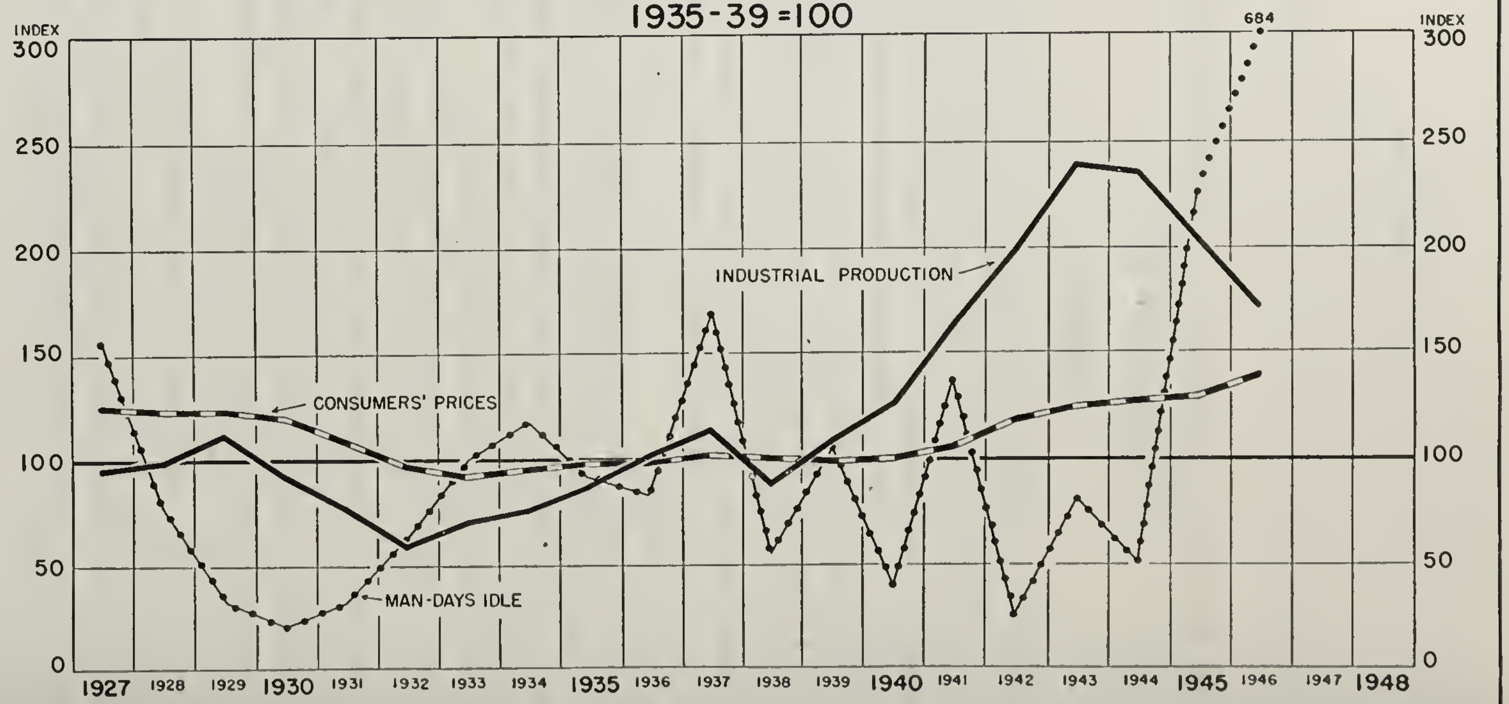
INDUSTRIAL PRODUCTION, CONSUMERS' PRICES, AND IDLENESS DURING WORK STOPPAGES

1935-39=100



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

loyment in nonagricultural establishments likewise averaged higher ian in prewar years and was about a third larger than in 1939.

Historically, 1946 is most comparable to 1919, the first full year llowing World War I, when rising prices and union recognition or curity were among the major problems confronting American dustry and wage earners. The 3,630 strikes in 1919 involved well ver 4.1 million workers (table 1). Information on time lost is not vailable for years prior to 1927, but incomplete records indicate that iere was less idleness in 1919 than in 1946. The number of workers rectly involved in work stoppages, however, represented a larger roportion of that part of the labor force which might have been fected by strikes in 1919 than was the case in 1946—about 21 percent s against 14½ percent.

TABLE 1.—*Work stoppages in the United States, 1916 to 1946*

Year	Work stoppages		Workers involved		Man-days idle			Indexes (1935–39=100)		
	Number	Average duration (calendar days)	Number (thousands) [1]	Percent of total employed [2]	Number (thousands)	Percent of estimated working time [3]	Per worker involved	Work stoppages	Workers involved	Man-days idle
16 [1]	3,789	(4)	1,600	8.4	(4)	(4)	(4)	132	142	(4)
17	4,450	(4)	1,230	6.3	(4)	(4)	(4)	155	109	(4)
18	3,353	(4)	1,240	6.2	(4)	(4)	(4)	117	110	(4)
19	3,630	(4)	4,160	20.8	(4)	(4)	(4)	127	370	(4)
20	3,411	(4)	1,460	7.2	(4)	(4)	(4)	119	130	(4)

[1] The number of workers involved in some strikes which occurred from 1916 to 1926 is not known. The issing information is for the smaller disputes, however, and it is believed that the totals here given are rly accurate.

[2] "Total employed workers" as used here refers to all workers except those in occupations and professions which there is little if any union organization or in which strikes rarely, if ever, occur. In most industries includes all wage and salary workers except those in executive, managerial, or high supervisory positions those performing professional work the nature of which makes union organization or group action imprac-able. It excludes all self-employed, domestic workers, agricultural wage workers on farms employing s than 6, all Federal and State government employees, and the officials (both elected and appointed) in al governments.

[3] Estimated working time was computed for purposes of this table by multiplying the average number of nployed workers each year by the number of days worked by most employees during the year.

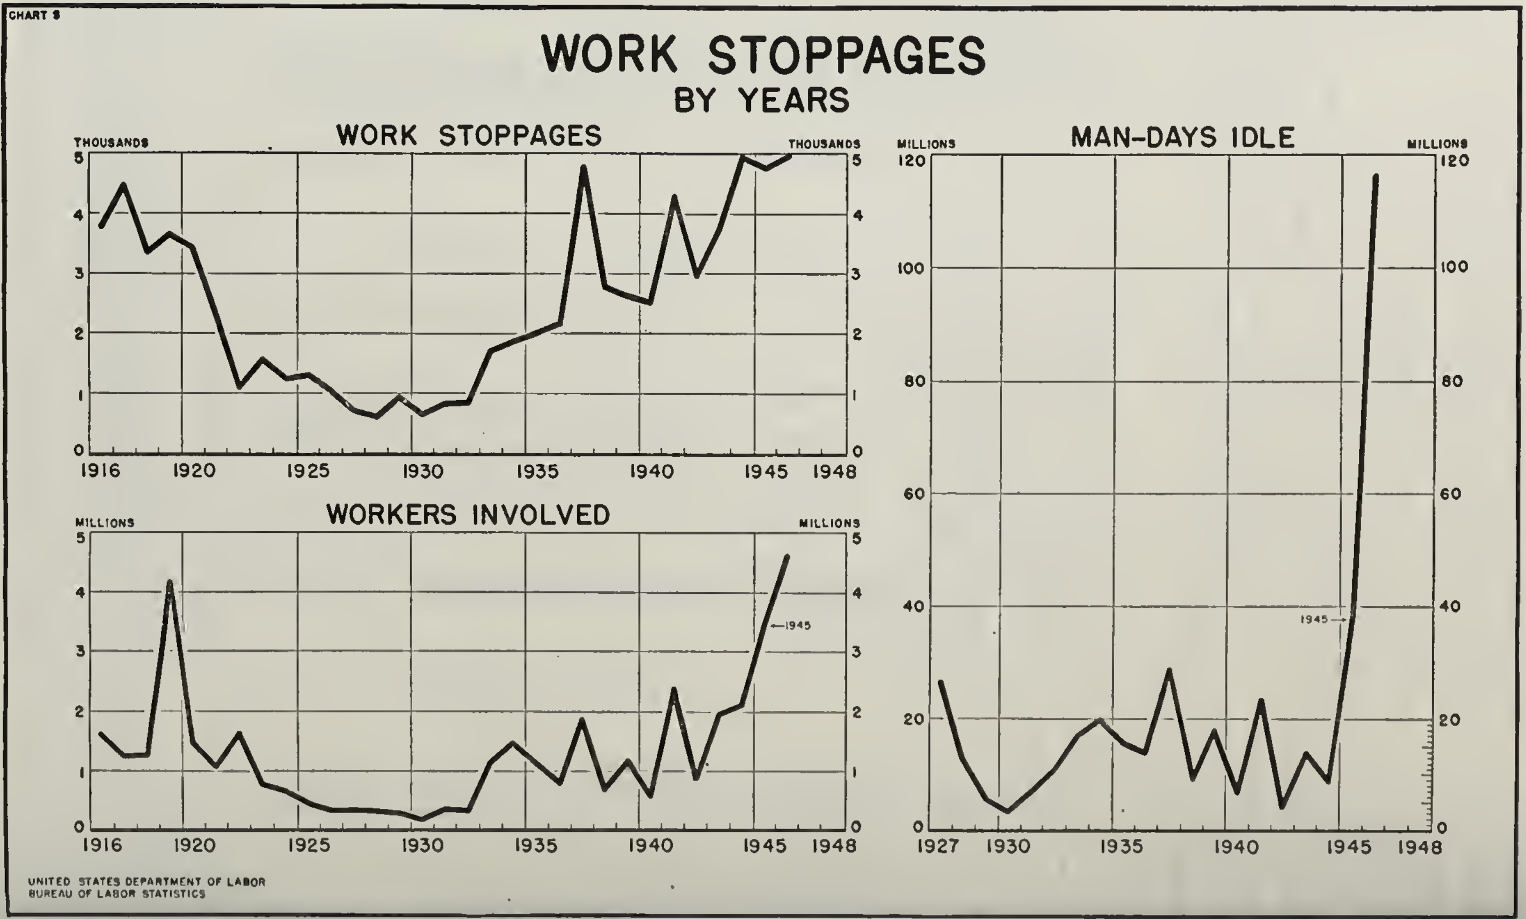
CHART 8



WORK STOPPAGES BY YEARS

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Interpretation of the Data

All known work stoppages in the United States that resulted from abor-management disputes which involved six or more workers and ontinued as long as a full day or shift are covered in this as in previous reports.[3] Information on "workers involved" and "man-days dle" includes all workers made idle in establishments directly involved n stoppages. The data do not measure the indirect or secondary ffects of stoppages on other establishments or industries whose emloyees are made idle as a result of material or service shortages

The Bureau's statistical series on work stoppages does not reflect, xcept indirectly, the degree to which the customary practices of ollective bargaining succeed in settling the overwhelming proportion f labor controversies. Some perspective on this generally unpubliized pattern of peaceful negotiations between unions and employers may be obtained by noting that in 1946 approximately 14.8 million workers were covered by collective-bargaining agreements negotiated by the representatives of some 50,000 to 60,000 local unions with an even larger number of employers. Although the number of union agreements in effect is not known, the Bureau estimates that this total is substantially in excess of 50,000. Most agreements are revised or amended annually; some are effective for longer periods. Many of these, however, contain a "reopening" clause permitting the renegotiation of certain provisions (usually those covering wages) during the life of the agreement. It may therefore be conservatively estimated that 50,000 or more agreements are rewritten in whole, or in part, each year, mostly without a work stoppage and in some cases even without a serious dispute requiring the aid of a third party.

Records of Federal and State conciliation and mediation agencies show that the number of disputes settled without recourse to interruptions of work far outnumber those which result in work stoppages. The United States Conciliation Service of the Department of Labor, for example, assisted in the adjustment of over 15,000 labor-management controversies in 1946. About 3 out of every 4 of these disputes were settled peacefully without an interruption of work. Reports of the National Mediation Board, regarding labor relations on the Nation's railroads and airlines, and the experiences of various State and local mediation agencies reflect a similar picture.

The fact that most labor-management differences were settled amicably does not, of course, minimize the gravity, or intensity, of some work stoppages which occurred in 1946. A few, such as those in steel, mining, and transportation, were extremely serious and disruptive to the general economy. In addition, a small number of localized stoppages, notably in the utility and service industries, temporarily inconvenienced many times the number of workers who were actually involved in these disputes. Other stoppages, also relatively few in number, found the employer and sometimes the general public caught in a cross-fire between two or more union groups.

---

[3] For a fuller discussion of the scope and method of work-stoppage statistics used by the Bureau, see Work Stoppages in 1945, Monthly Labor Review, May 1946 (pp. 734-735).

It is equally true, however, that for each disruptive work stoppage there were many significant labor-management disputes which were settled peacefully during the year. Thus, the "Big Four" rubber companies negotiated a wage agreement amicably in March 1946; settlement of a Nation-wide telephone dispute was reached without any interruption of service; and a million railroad workers, representing all but two of the major railway unions, voluntarily agreed to arbitrate their wage demands. A scheduled national maritime stoppage was averted in June. Building-trades workers in many cities throughout the country reached mutually satisfactory understandings with their employers. The automobile industry experienced one serious stoppage, but agreements with some of the large producers were negotiated without interruptions to production. Thousands of workers and employers in many industries, continued to resolve their differences in 1946, as in preceding years, without recourse to work stoppages.

Background to 1946 Stoppages

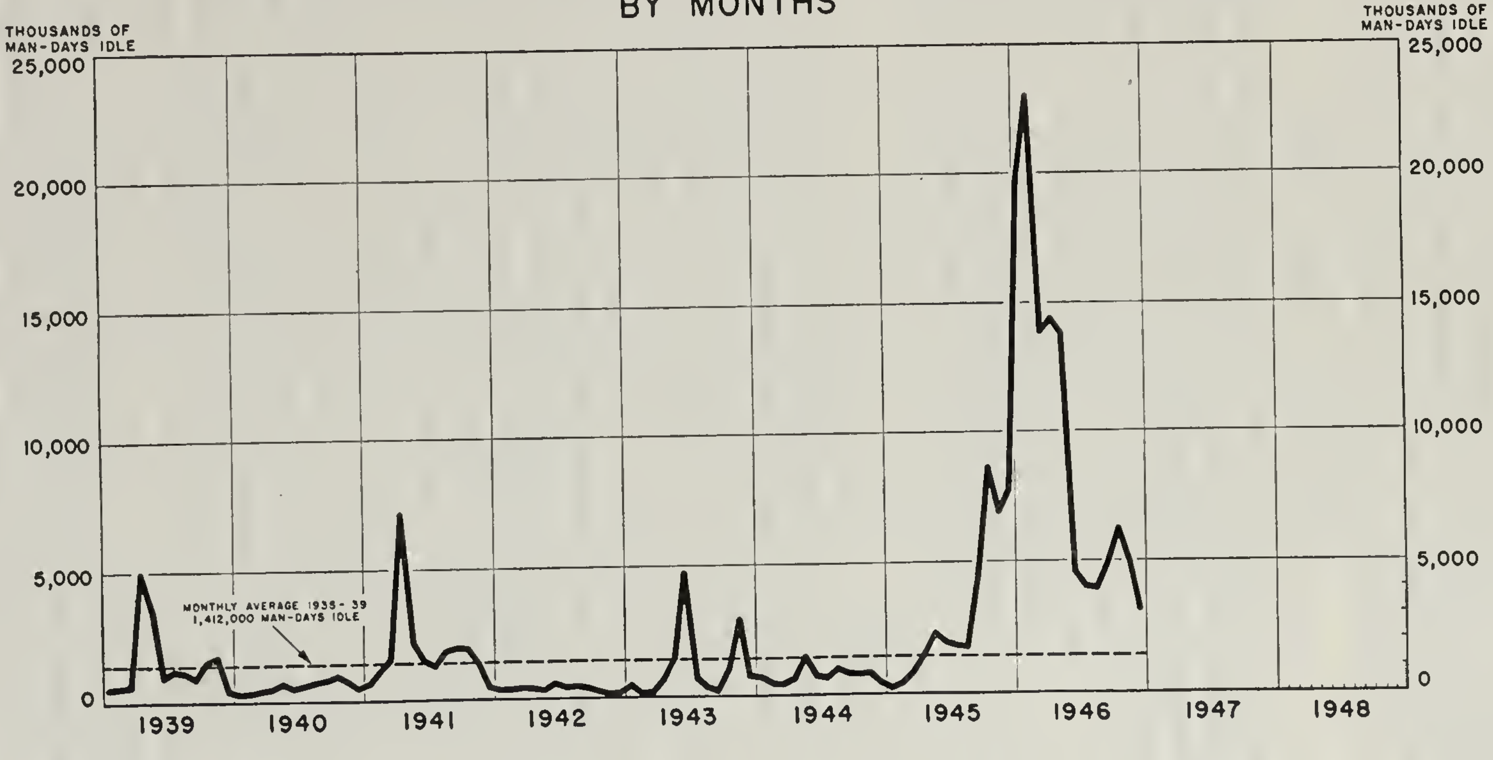
Between VJ-day and the end of 1945, relations between organized labor and management became increasingly strained. Labor's no-strike and management's no-lock-out pledges were dissolved. Patriotic and emotional ties which bound the Nation together so successfully in achieving phenomenal wartime production records were ineffectual when the economic realities of reconversion were faced. Workers were concerned about losses in earnings and rises in prices, and employers about governmental controls, reconversion problems, and new markets for their products. Both labor and management spoke hopefully about a return to "free collective bargaining," but, as the President's National Labor-Management Conference of November 1945 revealed, wide areas of disagreement still prevailed. The functions of the National War Labor Board, which had served effectively as a tribunal of final appeal during the war, were reduced, and this agency finally went out of existence on December 31, 1945.

The cleavage was also evidenced by the apparent inability of labor and management to resolve their differences without costly work stoppages. Disputes which during the war had been settled amicably, or with relatively brief interruptions to production, required weeks and even months to adjust. Approximately 75 percent of all the idleness due to work stoppages in 1945 occurred in the 4½ months following VJ-day (table 2). Many disputes which began in the autumn continued throughout the winter. As the year 1945 ended, about 370,000

CHART 3

TREND IN IDLENESS DUE TO WORK STOPPAGES

BY MONTHS



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

workers were idle in 165 controversies. Included in this total were some 8,000 Northwest lumberjacks who had been on strike from late September; 13,000 glass workers and 37,000 San Francisco machinists and shipyard workers who had stopped work in October; and nearly a quarter of a million auto workers, textile-mill hands, and truck drivers who had quit their jobs for picket lines during November 1945.

Trend of Strike Activity in 1946

With the coming of the New Year, other momentous disputes were destined to result in stoppages, because, in many instances, prolonged negotiations were unsuccessful. On December 31, 1945, President Truman appointed a fact-finding board in the hope of averting a steel strike. In September of that year, the United Steelworkers of America (CIO) had submitted its demands for a $2-a-day wage increase, which had been rejected by the industry. AFL and CIO packing-house workers had sought upward revisions in pay since August 1945. Representatives for more than a million railroad workers were conferring with carrier representatives over questions of higher wages.

By mid-January 1946 negotiations gave way to strike action. Approximately 174,000 employees of three large electrical manufacturing concerns stopped work January 15. Conferences between these companies and the United Electrical, Radio, and Machine Workers of America (CIO) had been in progress since the autumn of 1945. A day later 93,000 AFL and CIO workers of major meat-packing houses walked out. Less than a week afterward (January 21) the country's steel furnaces and mills ceased operations. The steel strike, involving over 1,000 large and small basic steel producers and fabricators and about 750,000 workers, was the largest strike ever recorded in the United States. At the height of these and of about 250 smaller disputes then in progress the number of workers directly involved in labor-management work stoppages approximated 1,600,000.

The controversy between the steel workers and the largest steel producer, the United States Steel Corp., was terminated February 15 with agreement by the parties to accept a wage increase of 18½ cents previously recommended by President Truman. Settlements were reached with several other large basic-steel producers in the next few days; but, in the case of many smaller steel fabricators, the stoppage continued for weeks pending adjustment of local union-management issues and clarification of the extent to which increases in steel prices were to be permitted by the OPA.

Idleness, which in January had mounted to a record-breaking total of 19.7 million man-days, climbed still further in February to approximately 23 million man-days. In March, however, this figure was lmost halved, as both the UAW[4]–General Motors and the UE[5]–General Electric disputes were terminated. The number of smaller toppages rose, however, partly because many union-management ontracts expired and partly because of the widespread desire of orkers for wage increases in line with the 18½-cent pattern which volved out of the steel settlement and the mid-February revision of he Government's wage-stabilization regulations.

April marked a further upturn in the number of strikes. Idleness lso increased as the industry-wide controversy between the bituminous-coal operators and the United Mine Workers of America (AFL) rought a suspension of work by 340,000 soft-coal miners beginning pril 1. This dispute continued into May, so that little bituminous oal was produced during that month, except for a 2-week truce in id-May. On May 22 the Government seized the coal mines and week later it concluded an agreement with the union.

The crisis in railroad labor-management negotiations also reached the breaking point, and the Government took control of the railroads n May 17. But this action, as well as the intercession by the White House, failed to forestall a Nation-wide 2-day strike of two large naffiliated railroad unions—the Brotherhood of Locomotive Engineers and the Brotherhood of Railroad Trainmen. These two organizations had rejected the recommendations on wages and rules of a presidentially appointed fact-finding board, and their 48-hour suspension of work, from May 23 to May 25, paralyzed rail transportation throughout the country.

With the settlement of the railroad controversy, the 2-months' bituminous-coal strike, and the 8-day stoppage of 75,000 anthracite miners (the latter settled early in June), labor-management stoppages of large industry-wide proportions momentarily ended. For the first time since September 1945 idleness in June dropped below 5 million man-days. The first 6 months of 1946, however, had marked the most concentrated period of labor-management strife in the country's history. Although less than half of the year's total number of work stoppages began in the first half of 1946, these were by far the largest of any recorded during the year. They involved approximately 2,970,000 workers and, including stoppages carried over from 1945, resulted in 88.9 million man-days of idleness—77 percent of the year's total lost time, estimated at 116 million man-days.

During the 2 summer months of July and August, 1,100 stoppages occurred. Most of these dealt with wage issues. Virtually all were small, affecting relatively few workers, and idleness during each of these 2 months averaged less than in any month after VJ-day.

[1] See footnote 2 to table 1.

[2] See footnote 3 to table 1.

September, however, brought a generally higher rate of strike activity. A serious disruption of trucking operations in and about New York City began the first of the month. On September 5 the Seafarers' International Union of North America (AFL) called a Nation-wide cessation of work after the National Wage Stabilization Board refused to approve wage increases for unlicensed seamen higher than those previously approved in June for similar groups in the National Maritime Union of America (CIO). This stoppage was characterized by AFL leaders as a protest against Government "interference" with "free collective bargaining." The stoppage was also supported by AFL and CIO longshoremen and seamen. The dispute, insofar as the Seafarers' International Union was concerned, was settled with a Government directive amending the stabilization regulations then applicable. The National Maritime Union, however, insisted that the unlicensed seamen whom it represented should have their contracts amended to incorporate the higher wage rates obtained by the AFL seamen's union. This controversy was resolved in favor of the workers after a further stoppage of approximately 10 days.

Not all of the more than 750 deep-sea vessels tied up in the AFL nd CIO stoppages of unlicensed maritime workers had weighed nchor before the expiration of contracts on September 30 between hip operators and licensed seamen. These workers, represented y the Masters, Mates, and Pilots of America (AFL) and the National Iarine Engineers' Beneficial Association (CIO), sought to have ncluded in their new collective bargaining agreements a greater legree of union recognition or "security," together with higher vages. On the Pacific Coast, contracts between the International ongshoremen's and Warehousemen's Union (CIO) and various vaterfront employers also had expired on September 30 without the arties agreeing on new terms. Over 1,000 ships were landlocked by hese stoppages, and the total number of workers idle was estimated t approximately 142,000. On the East and Gulf Coasts, settle-nents between the two licensed groups of maritime employees and hip operators were reached by the end of October, but on the West Coast the disputes involving seamen and longshoremen continued or nearly a month longer.

The autumn maritime stoppages raised the number of workers nvolved in labor-management disputes above the level of the months mmediately preceding. Idleness totaled nearly 5 million man-days in September and over 6 million man-days in October. In November, the lost time of almost 5 million man-days was substantially affected by the second industry-wide bituminous-coal stoppage which began November 21 and continued through December 7. In this controversy the Government, which had been operating the mines under the so-called Krug-Lewis agreement of May 29, 1946, insisted that the United Mine Workers could not unilaterally terminate their contract. After the miners suspended work the Government sought, and obtained, a Federal court order instructing union officials to terminate the stoppage and the miners to resume work. When the terms of the court's order were not complied with, Justice T. Alan Goldsborough of the United States District Court of the District of Columbia fined the union $3,500,000 and its president, John L. Lewis, $10,000 for contempt of court. The miners were ordered back to work by Mr. Lewis on December 7, and both the union and the Government took prompt steps to bring the legal issues in dispute before the United States Supreme Court.[6]

---

[6] On March 6, 1947, the Supreme Court ruled that the anti-injunction provisions of the Norris-LaGuardia Act were not applicable to the federally operated bituminous-coal mines. The Court upheld the lower court's contempt conviction but ruled that the fine against the United Mine Workers was to be reduced from $3,500,000 to $700,000, provided the union withdrew its contract termination notice. Action to this effect was taken by the UMWA president on March 19 and on April 24 Justice Goldsborough ordered a refund of $2,800,000.

With the termination of the bituminous-coal controversy, strike activity dropped to its lowest level since VJ-day. The number of stoppages beginning in December totaled 168 and workers involved aggregated less than 80,000. At the year's end, fewer than 60,000 workers were idle in the 160 labor-management controversies then in effect. Total idleness was only about an eighth as great as during the final weeks of 1945.

Characteristics of Work Stoppages in 1946

INDUSTRIES AFFECTED

The impact of the large labor-management controversies upon the Nation's industries is reflected in the data presented in table 3.[7] Although the large-scale stoppages in such industries as steel, meat packing, electrical manufacturing, and transportation accounted for a high proportion of the total time lost, there were significant or unusual stoppages in a number of industries not disclosed by the over-all statistics. Thus, controversies involving relatively small numbers of public-school teachers, municipal employees, and utility workers had a widespread effect upon their communities. Teachers, as members of the "white collar" or "fixed income" group, were among those salaried workers particularly hard-pressed by rising living costs. They participated in 16 stoppages during the year—an unusually high number as compared with previous years. Municipal workers, whose wages in many instances are also comparatively inelastic, ceased work in some 60 cases in efforts to improve their pay or conditions of employment.

Twenty-four stoppages occurred in the heat, light, and power industries. In most of these disputes essential services were generally continued—in some cases with the aid of supervisory personnel—and settlements were usually reached in a relatively few days. The most serious and largest utility strike of the year involved the Duquesne Light Co. and associated companies in the Pittsburgh area. This stoppage continued for 27 days and disrupted commercial and industrial activity in a large segment of western Pennsylvania.

Public attention was also focused on stoppages in urban and interurban public transportation systems. Philadelphia, Los Angeles, and Detroit were among the larger cities affected by such localized controversies. Shipments of express, parcels, and freight in and about New York City were substantially curtailed on several occasions because of trucking strikes. Operations of a large air-transport company were temporarily suspended as a result of the first strike of airline pilots in the history of the country. There were also a few serious ork stoppages involving local telephone, telegraph, and wireless ompanies. As a result of these and other larger stoppages previously escribed, more workers were directly involved in labor-management ontroversies in the field of transportation, communication, and public tilities in 1946 than in any previous year on record.

---

[7] Where workers in a particular industry were involved in 2 or more stoppages during the year, they were counted separately for each dispute. This explains why in some industries (bituminous-coal mining, for example) more workers were involved in work stoppages than the total number actually employed in these industries.

Table 3.—*Work stoppages beginning in 1946, by industry group*

Industry group	Stoppages beginning in 1946			Man-days idle during 1946	
	Number	Workers involved			
		Number	Percent of total employed [2]	Number	Percent of estimated working time [2]
ll industries	[1] 4,985	4,600,000	14.5	116,000,000	1.43
anufacturing	[1] 2,887	2,210,000	16.7	81,700,000	2.42

---

[1] The total number of stoppages shown is less than the sum of the group figures which follow. The reason s, a few strikes which extended into 2 or more industry groups have been counted separately (in this table) n each industry group affected, except in the totals for all industries, with allocation of workers involved and man-days idle to the respective groups. Not included in this table were 3 strikes of a general or city-wide character (at Rochester, N. Y., Oakland, Calif., and Portland, Maine) which involved 74,000 workers and 128,000 man-days of idleness.

[2] See footnotes 2 and 3 to table 1.

[3] Not available.

[4] The number of workers involved was greater than the total employed in the mining industry; many workers participated in more than 1 stoppage during the year and were counted separately each time. Most bituminous-coal miners were out twice during the year.

TABLE 4.—*Work stoppages in 1946, by specific industry* [1]

Industry	Number of stoppages beginning in 1946	Number of workers involved [1]	Man-days idle during 1946 [1]
All industries	[2] 4, 985	4, 600, 000	116, 000, 000
Manufacturing			
Iron and steel and their products	[2] 478	859, 000	23, 500, 000
Ordnance and accessories	3	240	27, 600
Blast furnaces, steel works, and rolling mills	89	493, 000	10, 800, 000
Iron and steel foundry products	80	99, 300	2, 690, 000
Tin cans and other tinware	11	14, 700	549, 000
Wire products	23	12, 500	543, 000
Hand tools, cutlery, and general hardware	35	20, 200	1, 210, 000
Heating apparatus, enameled-iron sanitary ware, and boilershop products	108	94, 300	3, 490, 000
Metal stamping and coating	48	21, 500	726, 000
Fabricated structural metal products	31	37, 200	1, 020, 000
Miscellaneous iron and steel products	62	66, 000	2, 430, 000
Electrical machinery	[2] 134	232, 000	10, 800, 000
Electrical equipment for industrial use	53	149, 000	8, 120, 000
Electrical appliances	16	7, 280	232, 000
Insulated wire and cable	5	5, 410	147, 000
Aumotive electrical equipment	17	20, 700	457, 000
Electric lamps	4	100	4, 070
Communication equipment and related products	34	42, 600	1, 760, 000
Miscellaneous electrical products	13	7, 020	55, 600
Machinery (except electrical)	[2] 324	244, 000	13, 700, 000
Engines and turbines	10	19, 200	1, 380, 000
Agricultural machinery and tractors	51	68, 800	4, 400, 000
Construction and mining machinery	18	19, 900	959, 000
Metalworking machinery	67	24, 000	1, 050, 000
Special-industry machinery (except metalworking machinery)	63	23, 000	955, 000
General industrial machinery	78	55, 200	4, 190, 000
Office and store machines and devices	12	9, 860	153, 000
Household and service-industry machines	35	24, 200	568, 000
Transportation equipment (except automobiles)	[2] 61	59, 200	2, 340, 000
Railroad equipment	12	10, 800	311, 000
Aircraft and parts	15	21, 300	557, 000
Ships and boat building and repairing	31	25, 700	1, 380, 000
Motorcycles, bicycles, and parts	2	930	95, 100
Transportation equipment, not elsewhere classified	2	500	2, 500
Automobiles and automobile equipment	[2] 132	163, 000	15, 000, 000
Motor vehicles and motor-vehicle bodies	58	118, 000	13, 700, 000
Motor vehicle parts and accessories	71	43, 400	1, 240, 000
Automobile trailers	4	1, 790	29, 700
Nonferrous metals and their products	[2] 134	78, 200	4, 280, 000
Smelting, refining, and alloying of nonferrous metals	38	53, 200	3, 570, 000
Aluminum and magnesium products	16	9, 780	128, 000
Jewelry, silverware, and plated ware	11	1, 420	79, 900
Watches and clocks	8	770	34, 600
Engraving, plating, and polishing	14	1, 020	39, 100
Lighting fixtures	14	2, 400	94, 400
Miscellaneous nonferrous-metal products	38	9, 570	332, 000
Lumber and timber basic products	61	16, 400	959, 000
Sawmills and logging camps	39	13, 300	860, 000
Planing and plywood mills	22	3, 150	98, 600
Furniture and finished lumber products	[2] 208	44, 900	1, 550, 000
Furniture (household, office, etc.)	125	27, 300	854, 000
Office and store fixtures	10	1, 380	9, 230
Wooden containers	31	4, 020	139, 000
Window and door screens and shades	6	1, 280	25, 400
Morticians' goods	13	3, 030	98, 300
Miscellaneous wood products	26	7, 870	426, 000
Stone, clay, and glass products	[2] 136	32, 000	1, 180, 000
Glass and glass products	22	6, 160	339, 000
Cement	10	2, 180	51, 300
Structural clay products	40	9, 780	310, 000
Pottery and related products	14	4, 970	176, 000
Concrete, gypsum, and plaster products	26	3, 170	83, 30
Cut-stone and stone products	4	650	8, 660
Abrasive, asbestos, and miscellaneous nonmetallic mineral products	25	5, 100	212, 000

See footnotes at end of table.

TABLE 4.—*Work stoppages in 1946, by specific industry* [1]—Continued

Industry	Number of stoppages beginning in 1946	Number of workers involved [1]	Man-days idle during 1946 [1]
Manufacturing—Continued			
Textile-mill products	188	50,700	1,360,000
Cotton textile mills	55	19,300	812,000
Rayon and silk textile mills	13	3,540	151,000
Woolen and worsted textile mills	31	8,800	119,000
Knitting mills (except hosiery)	30	2,680	72,900
Dyeing and finishing textiles (except woolen and worsted)	9	1,520	12,700
Carpets, rugs, and other floor coverings	9	2,710	51,100
Hats (except cloth and millinery)	4	2,700	32,300
Hosiery mills	13	6,660	66,700
Miscellaneous textile goods	24	2,820	42,200
Apparel and other finished products made from fabrics and similar materials	173	24,300	574,000
Men's and boys' suits, coats, and overcoats	1	50	1,330
Men's and boys' shirts, work clothing, and allied garments	32	6,670	163,000
Women's and misses' outerwear	63	5,470	57,400
Women's undergarments and accessories	10	1,300	15,600
Millinery	2	30	670
Children's and infants' outerwear	27	1,330	11,500
Fur goods	4	110	990
Miscellaneous apparel and accessories	12	2,490	42,800
Miscellaneous fabricated textile products	22	6,810	281,000
eather and leather products	100	29,000	434,000
Leather—tanned, curried, and finished	22	2,690	105,000
Industrial leather belting and packing	2	270	15,700
Footwear (except rubber) including cut stock and findings	59	22,700	214,000
Leather gloves and mittens	2	2,090	51,200
Luggage	5	500	12,900
Handbags and small leather goods	6	600	27,900
Miscellaneous leather goods	4	160	6,930
Food and kindred products	278	167,000	2,220,000
Meat products	50	97,600	966,000
Dairy products	18	3,340	21,600
Canning and preserving fruits, vegetables, and sea foods	19	19,300	270,000
Grain-mill products	37	7,120	114,000
Bakery products	67	20,500	356,000
Sugar	3	880	58,800
Confectionery and related products	15	3,020	61,200
Beverage industries	46	9,900	189,000
Miscellaneous food preparations and kindred products	23	5,670	182,000
Tobacco manufactures	14	4,190	255,000
Cigarettes	----------	----------	165,000
Cigars	12	3,910	85,600
Tobacco stemming	2	270	5,150
Paper and allied products	76	21,500	606,000
Pulp, paper, and paperboard	34	12,200	386,000
Containers—paper and paperboard	28	4,460	170,000
Miscellaneous paper and allied products	14	4,800	49,700
Printing, publishing, and allied industries	67	14,200	326,000
Newspapers and periodicals	31	5,090	179,000
Books	2	90	3,110
Miscellaneous printing and publishing	34	9,050	143,000
Chemicals and allied products	[2] 122	48,100	1,190,000
Paints, varnishes, and colors	14	1,650	61,200
Vegetable and animal oils	9	1,770	21,100
Drugs, toilet preparations, and insecticides	17	2,440	84,600
Soap and glycerin	2	2,580	28,100
Wood distillation and naval stores	3	810	5,470
Fertilizers	12	1,520	25,600
Industrial chemicals	64	37,300	950,000
Miscellaneous chemical products	2	50	10,800
Products of petroleum and coal	21	4,280	108,000
Petroleum refining	12	1,980	28,900
Paving and roofing materials	9	2,290	78,800
Rubber products	89	99,400	813,000
Tires and inner tubes	40	78,000	492,000
Rubber footwear, heels and soles, and related products	9	5,120	42,000
Industrial rubber goods	25	13,400	228,000
Rubberized fabrics and vulcanized rubber clothing	1	270	28,200
Rubber sundries and sponge rubber	10	1,990	17,400
Miscellaneous rubber industries	4	600	4,740

See footnotes at end of table.

TABLE 4.—*Work stoppages in 1946, by specific industry* [1]—Continued

Industry	Number of stoppages beginning in 1946	Number of workers involved [1]	Man-days idle during 1946 [1]
Manufacturing—Continued			
Miscellaneous manufacturing industries	[2] 120	22, 900	612, 000
Professional and scientific instruments, photographic apparatus, and optical goods	34	10, 200	266, 000
Brooms and brushes	6	1, 270	85, 100
Musical instruments	3	1, 090	43, 300
Toys and sporting and athletic goods	13	1, 900	39, 700
Pens, pencils, and other office and artist's materials	10	1, 370	20, 400
Buttons	4	410	6, 940
Costume jewelry and miscellaneous novelties	10	700	25, 600
Fabricated plastic products	12	1, 370	39, 300
Miscellaneous industries	30	4, 630	86, 000
Nonmanufacturing			
Agriculture, forestry, and fishing	28	17, 500	219, 000
Agriculture	14	5, 610	64, 900
Fishing	14	11, 900	154, 000
Mining	570	974, 000	21, 400, 000
Metal mining	18	24, 600	1, 190, 000
Coal mining, anthracite	34	109, 000	649, 000
Coal mining, bituminous	485	834, 000	19, 500, 000
Crude petroleum and natural gas production	4	750	23, 800
Nonmetallic mining and quarrying	27	4, 700	46, 500
Miscellaneous	2	190	32, 400
Construction	351	146, 000	1, 450, 000
Building construction	312	141, 000	1, 340, 000
Highways, streets, bridges, docks, etc	31	4, 610	100, 000
Miscellaneous	8	670	10, 200
Trade	385	64, 100	882, 000
Wholesale	124	15, 500	207, 000
Retail	261	48, 760	675, 000
Finance, insurance, and real estate	29	2, 140	14, 700
Finance—banks, credit agencies, investment trusts, etc	2	140	500
Insurance	4	260	1, 860
Real estate	23	1, 740	12, 300
Transportation, communication, and other public utilities	479	1, 020, 000	9, 020, 000
Railroads	17	356, 000	912, 000
Streetcar and local bus transportation	54	33, 700	197, 000
Intercity motorbus transportation	62	12, 900	244, 000
Motortruck transportation	112	70, 600	1, 230, 000
Taxicabs	66	6, 890	69, 500
Water transportation	68	350, 000	5, 240, 000
Air transportation	2	14, 700	247, 000
Communication	24	159, 000	688, 000
Heat, light, and power	24	7, 620	57, 000
Miscellaneous	50	10, 700	140, 000
Services—personal, business, and other	206	54, 700	924, 000
Hotels	29	11, 500	265, 000
Laundries	41	5, 880	94, 500
Cleaning, dyeing, and pressing	14	1, 420	38, 500
Barber and beauty shops	8	4, 550	104, 000
Business services	14	620	10, 600
Automobile repair services and garages	22	890	12, 000
Amusement and recreation	28	24, 300	311, 000
Medical and other health services	4	110	2, 770
Educational services	26	4, 360	45, 100
Miscellaneous	20	1, 070	40, 200
Other nonmanufacturing industries	62	9, 660	51, 000
Government—administration, protection, and sanitation	62	9, 660	51, 000

---

[1] Not included in this table, except in the totals for all industries, were 3 strikes of a general or city-wide character (at Rochester, N. Y., Oakland, Calif., and Portland, Maine) which involved 74,000 workers and 128,000 man-days of idleness.

[2] This figure is less than the sum of the group totals below. This is because a few strikes, each affecting more than 1 industry, have been counted as separate strikes in each industry affected, with the proper allocation of workers and man-days idle to each industry.

TABLE 5.—*Work stoppages in 1946, by industry group and major issues involved*

Industry group	Number of stoppages beginning in 1946 in which the major issues were—					
	Wages and hours	Union organization, wages, and hours	Union organization	Other working conditions	Inter- or intra-union matters	Not reported
All industries	[1] 2,244	924	722	876	253	10
Manufacturing	[1] 1,304	674	404	383	119	3
Iron and steel and their products	224	94	53	97	10	--------
Electrical machinery	57	32	29	11	5	--------
Machinery (except electrical)	151	86	42	35	9	1

Trade	433,000	193,000	145,600	59,800	52,000	30
Finance, insurance, and real estate	1,470	8,600	2,720	1,150	770	--------
Transportation, communication, and other public utilities	4,810,000	3,560,000	239,006	241,000	166,000	--------
Services—personal, business, and other	513,000	64,600	92,100	8,640	245,000	--------
Other nonmanufacturing industries	21,800	20,000	6,080	3,080	----------	--------
General strikes [2]	----------	----------	----------	----------	128,000	--------

This figure is less than the sum of the figures which follow. This is because a few strikes, each affecting re than 1 industry, have been counted as separate strikes in each industry affected, with the proper cation of workers involved and man-days idle to each industry.

These were strikes of a general or city-wide character in Rochester, N. Y., Oakland, Calif., and rtland, Maine.

WORK STOPPAGES, BY STATES

Although New York had the largest number of work stoppages hich began in 1946, Pennsylvania's time loss occasioned by labor-anagement controversies was approximately twice as great as that r any other State (table 6). This, of course, reflects the importance the steel and coal industries in Pennsylvania. Michigan and hio each experienced over 10 million man-days of idleness and were osely followed by such other industrialized States as New York and linois. Stoppages in these five States combined accounted for about alf of the country's total idleness.

TABLE 6.—*Work stoppages in 1946, by States*

---

[1] The sum of this column is more than 4,985, because the stoppages extending across State lines have been counted as separate stoppages in each State affected, with the proper allocation of workers involved and man-days idle.

[2] Less than a tenth of 1 percent.

WORK STOPPAGES, BY CITIES

Four cities—New York, Chicago, Detroit, and Philadelphia—each experienced over 100 work stoppages in 1946, and 100 other cities (table 7) experienced 10 or more stoppages. Idleness directly arising out of labor-management disputes exceeded 1,000,000 man-days in 10 cities—Buffalo, Chicago, Cleveland, Detroit, Houston, Los Angeles, New York, Philadelphia, Pittsburgh, and San Francisco.

TABLE 7.—*Work stoppages in 1946 in cities which had 10 or more such stoppages during the year* [1]

---

[1] Intercity stoppages, except those noted below, are counted in this table as separate stoppages in each city affected, with the proper allocation of workers involved and man-days idle to the respective cities. In a few instances it was impossible to secure the detailed data necessary to make such allocations. Therefore, the following stoppages are not included in the figures for any cities affected: (1) the Nation-wide railroad strike involving 350,000 workers in May, (2) the Oakland, Calif., area general strike involving 50,000 in December, (3) a dispute involving 5,000 employees of food canners and processors in and around the area east of Oakland, Calif., in March, (4) a strike against the Truck Owners Association of California involving 3,000 workers in September, and (5) a strike of 5,000 lumbermen in the Columbia Basin area of Oregon and Washington in September and October.

MAJOR ISSUES INVOLVED[8]

About half of the stoppages ending in 1946 arose over problems associated with the negotiation of initial agreements or changes in the provisions of existing collective-bargaining agreements. Wages were the most important single issue. The concern of workers over their ability to maintain, if not increase, their earnings was matched by doubts on the part of many employers as to the speed with which reconversion would be accomplished, the extent to which wage increases might be offset by price relief, and future trends in productivity and profits. As living costs rose, especially during the latter part of 1946, real earnings declined. Wages, or wage-and-hour problems combined, became the key issue in about 45 percent of all work stoppages which ended in 1946 (table 8). These stoppages involved 75 percent of all workers and about 82 percent of the recorded idleness. If to the above "wage-and-hour" group are added stoppages in which wage matters were combined with questions of union organization, wages were of major concern in 63 percent of the stoppages, which included 84 percent of the workers involved and 95 percent of the man-days of idleness.

Wages were also a factor in some disputes in which other issues, or groups of issues, appeared to dominate. In fact, the diversity and complexity of the causes or issues involved in work stoppages present difficult problems of classification for statistical purposes. Frequently, a considerable array of proposals and counterproposals are presented in the initial negotiations. Some of the proposals are for "trading purposes"; others represent the basic changes each party seeks to attain. Even these economic factors, if accurately appraised, do not take into account the human element—the psychology of the workers, the attitude of the employer, the strategy and tactics of union leaders—which, at times, may substantially determine which particular issue, or group of issues, will emerge as the hard core of the controversy. As a guide to the analysis of these problems, the Bureau endeavors to obtain from the parties directly involved their opinion as to the major issues in dispute. From the information thus furnished, together with other data available to the Bureau, each stoppage is classified in the manner set forth in table 8.

Problems of union organization—recognition of a labor organization by an employer, strengthening of the bargaining position, demands for a closed or union shop, and related questions—were the major factor in about 1 strike out of 7. Relatively few (2.6 percent) of the year's stoppages arose over the closed or union shop, and they involved less than 1 percent of the total number of workers affected by all stoppages. Including those additional instances in which wages were also a key issue, questions over the union or closed shop figured prominently in about 1 of every 10 stoppages ending in 1946.

---

[8] The data in this and most of the following sections of the article relate to stoppages *ending* in the calendar year 1946. Thus a number of large disputes which began in 1945 and terminated in 1946 are included. These stoppages more than offset those which began in 1946 but had not ended by the close of the year. This explains, for example, the total idleness figure of 124,000,000 man-days in table 8.

TABLE 8.—*Major issues involved in work stoppages ending in 1946* [1]

Major issue	Stoppages		Workers involved		Man-days idle

[1] It should be noted that this and most of the subsequent tables are based on the stoppages ending in the year and that the totals differ from those in preceding tables, which show the number of stoppages beginning in the year.

[2] Less than a tenth of 1 percent.

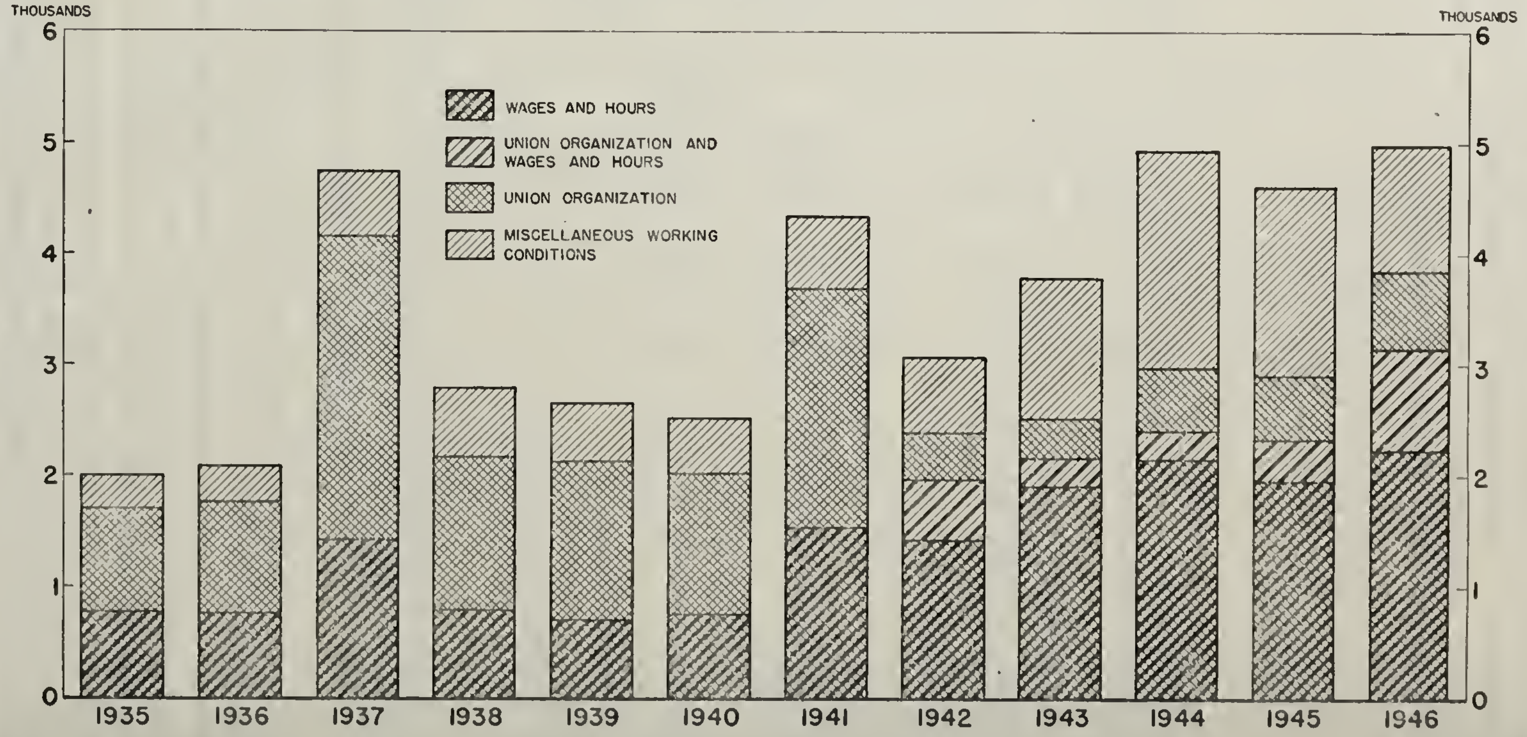
[3] Includes stoppages involving adjustments of piece rates, incentive rates, wage classifications for new and changed operations, retroactive pay, holiday and vacation pay, payment for travel time, etc.

Stoppages arising over interunion or intraunion matters, which included issues involving sympathy, union rivalry or factionalism, and jurisdiction, remained comparatively low, but they, nevertheless, attracted considerable public attention. The spotlight, in particular, was focused on those disputes which were not directed against employers but were primarily conflicts between union groups, generally called "jurisdictional strikes." The Bureau classifies these disputes as rival union strikes (those between unions of different affiliation) and jurisdictional strikes (those between unions belonging to the

CHART 4

MAJOR ISSUES INVOLVED IN WORK STOPPAGES

NUMBER OF WORK STOPPAGES



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

same affiliated body). Combined, these two issues accounted for only 3.5 percent of the stoppages ending during the year, a little more than 1 percent of the workers, and about half of 1 percent of the total amount of lost time.

Outstanding as an example of a jurisdictional struggle has been the intermittent strife in Hollywood between the Conference of Studio Unions, made up primarily of AFL craft affiliates, and the more inclusive AFL International Alliance of Theatrical Stage Employees.[9] Illustrative of disputes involving union rivalry was the controversy in which the Seafarers International Union (AFL) picketed piers in New York City and other Atlantic ports urging AFL workers to refuse to handle cargo of CIO ships unless the International Longshoremen's and Warehousemen's Union (CIO) abandoned its boycott against AFL-manned ships on the West Coast.

About 1 out of every 100 stoppages involved a sympathy demonstration in which other unions ceased work to support the strike of a particular group of employees or to protest action taken by a group of employers or a public agency. In April such a sympathetic strike tied up the Port of Philadelphia when both AFL and CIO unions supported the United Harbor Workers, affiliated with District 50, United Mine Workers (AFL). The following month both AFL and CIO unions of Rochester, N. Y., staged a 1-day general stoppage to protest the refusal of the city to recognize or bargain collectively with the AFL Federation of State, County, and Municipal Employees and the city's action in discharging 500 employees in the public works department seeking to form a union. The 2-day Oakland general strike in December 1946 involved 50,000 workers. It arose as a protest against a police escort given to alleged strikebreakers by the city administration through picket lines of the AFL Retail Clerks' International Protective Association.

DURATION

The average duration of work stoppages ending in 1946 was about 24 calendar days. This simple unweighted average of all strikes, irrespective of number of workers involved, was higher than for any time since the predepression years of 1927 and 1928. It exceeded the relatively high averages which prevailed in the late 1930's during the period of intense union organizational activity. The 1946 average was more than double that of the preceding year, and 3 to 4 times as long as during the war period.

Controversies lasting 3 months or longer constituted about 6 percent of total stoppages (table 9). The significance of this group in the general strike picture, however, was more far reaching than this per-

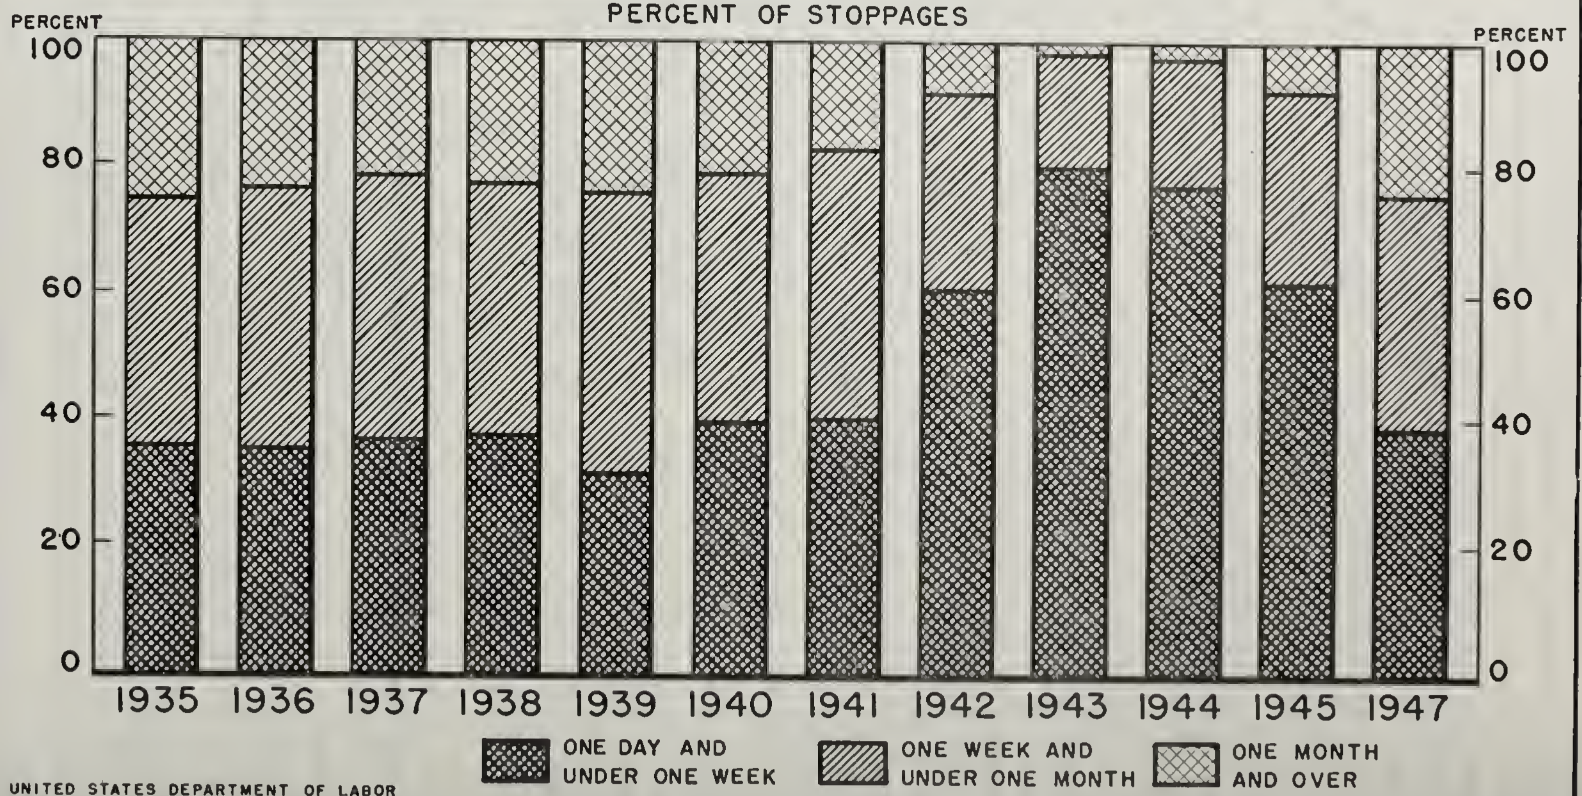
PERCENT OF STOPPAGES



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

centage figure indicates. These prolonged controversies involved about a seventh of all the workers and between a third and a half of the time loss. By contrast, in 1945, only 1 strike out of every 200 continued as long as 3 months, and time lost from these stoppages comprised but a twenty-fifth of the year's total.

Of the 303 stoppages which lasted 3 months or longer, 33 involved 1,000 or more workers. Included in this group of large strikes were such prominent disputes as those involving the nonferrous metal vorkers, auto builders of Mack Truck Co. and Diamond Motors, employees of Pratt and Whitney and Yale and Towne, and California redwood lumber workers. A number of plants of the Allis-Chalmers Co., were affected by labor-management stoppages which continued for varying periods ranging from 5 to 11 months. In addition, a few strikes which began in 1945 continued throughout the entire year 1946. These included the controversy between 13 railroad unions and the Toledo, Peoria, and Western Railroad which began October 1, 1945, a Southern textile strike, and the UAW–J. I. Case dispute. The last stoppage was terminated March 9, 1947. Issues of wages or wages and union security were the principal points of disagreement in most of these prolonged controversies.

TABLE 9.—*Duration of work stoppages ending in 1946*

Duration	Stoppages		Workers involved		Man-days idle	
	Number	Percent of total	Number	Percent of total	Number	Percent of total

WORK STOPPAGES, BY NUMBER OF WORKERS INVOLVED

About half of the stoppages in 1946 were small, involving fewer than 100 workers each. Groups of 100 to 500 workers were involved in a third of the stoppages, and a sixth of the total stoppages involved 500 or more workers each. The data in table 10 show for each industry group the size of the stoppages in terms of the number of workers involved. The average number of workers involved per strike was 923.

TABLE 10.—*Work stoppages beginning in 1946, classified by number of workers involved and industry group*

Industry group	Number of stoppages[1]	Median number of workers involved	Number of stoppages in which the number of workers involved was—							
			6 and under 20	20 and under 100	100 and under 250	250 and under 500	500 and under 1,000	1,000 and under 5,000	5,000 and under 10,000	10,000 and over

---

[1] The total number of stoppages shown for each industry group may differ from the number shown for the corresponding group in tables 3, 4, and 5 because of the fact that in those tables each stoppage extending into more than one industry group is counted as a separate stoppage in each group affected. In table 10 such stoppages are shown at the end as "interindustry" stoppages.

[2] These were strikes of a general or city-wide character in Rochester, N. Y., Oakland, Calif., and Portland, Maine.

MAJOR STOPPAGES

The 31 stoppages beginning in 1946 in which 10,000 or more workers were involved are listed separately in table 11. These 31 stoppages involved 2,925,000 workers (64 percent of the year's total) and resulted in 67,000,000 man-days of idleness (58 percent of the yearly total).

Table 11.—*Work stoppages beginning in 1946 in which 10,000 or more workers were involved*

Beginning date	Approximate duration (calendar days)	Establishment(s) and location	Union(s) involved	Major terms of settlement	Approximate number of workers involved
Jan. 3	65	Western Electric Co., New Jersey and New York.	Western Electric Employees Association—affiliated with National Federation of Telephone Workers (Ind.).	Wage increase of 18.2 percent retroactive for 5 weeks prior to Mar. 9.	24,000
Jan. 9	7	Western Electric Co., Nation-wide	Association of Communication Equipment Workers—affiliated with National Federation of Telephone Workers (Ind.).	Equipment workers returned to work under union orders pending formal strike action by National Federation of Telephone Workers. Mar. 9 wage increase of 5 cents an hour retroactive to Apr. 21, 1945, plus a 16.4 percent wage increase retroactive to Feb. 2, 1946.	142,000
Jan. 15	(1)	Electrical Manufacturing: General Motors, General Electric, and Westinghouse plants.	United Electrical Workers (CIO)	Wage increases of 18½ cents per hour for employees of General Motors and General Electric. Westinghouse workers obtained 18-cent increase with establishment of a fund of 1 cent an hour per employee to adjust differentials between men and women.	174,000
Jan. 16	19	Meat-packing Industry, several States	United Packinghouse Workers (CIO) and Amalgamated Meat Cutters (AFL).	Wage increase of 16 cents an hour	93,000
Jan. 21	(2)	Steel, industry-wide	United Steelworkers (CIO)	Wage increase of 18½ cents an hour	750,000
Do	86	International Harvester Co., Illinois, Indiana, Iowa, and New York.	United Farm Equipment Workers (CIO)	Wage increase of 18 cents an hour	29,000
Jan. 29	29	Caterpillar Tractor Co., Peoria, Ill	United Farm Equipment Workers (CIO)	Wage increase of 15 cents an hour for employees earning $1 an hour or less, and 15 percent for those earning more than $1 an hour. Maintenance of membership provision established with 15-day escape clause.	17,000
Feb. 4	(3)	American Brass Co. and Chase Brass Co., Connecticut and New York.	Mine, Mill, and Smelter Workers (CIO)	Wage increase of 18½ cents an hour for employees of both companies. Cash settlement of one-half million dollar compensatory bonus for wartime swing-shift workers of American Brass Co.	16,000
Feb. 11	2	Philadelphia Transit Co	Transport Workers (CIO)	Wage increase of 12 cents an hour and strengthened maintenance of membership clause (preferential shop).	10,000
Mar. 14	(4)	Allis-Chalmers, 7 plants in 6 States	United Automobile Workers (CIO), United Farm Equipment Workers (CIO), United Electrical Workers (CIO), and CIO Industrial Union, 1424.	Agreements signed at various times for different plants provided 13½-cent hourly wage increase and adjustments on such issues as seniority, vacation pay, job evaluation, and grievance procedure.	25,000

See footnotes at end of table.

TABLE 11.—*Work stoppages beginning in 1946 in which 10,000 or more workers were involved*—Continued

Beginning date	Approximate duration (calendar days)	Establishment(s) and location	Union(s) involved	Major terms of settlement	Approximate number of workers involved
Apr. 1	59	Bituminous Coal Mines, industry-wide	United Mine Workers (AFL after Jan. 1946)	Basic wage increase of 18½ cents an hour; welfare fund established based upon 5-cents a ton levy on each ton produced for use or sale.	340,000
Apr. 5	6	Port of Philadelphia	CIO and AFL unions in support of the United Harbor Workers (District 50, United Mine Workers, AFL).	CIO and AFL sympathy strikers, who refused to cross picket lines of the United Harbor Workers, returned to work when pickets were withdrawn.	18,000
May 3	1	Briggs Manufacturing Co., Detroit, Mich	United Automobile Workers (CIO)	Work resumed following a 1-day stoppage in protest against the discharge of 4 employees over production standard issue.	11,000
May 23	2	Railroad Industry, Nation-wide	Brotherhood of Locomotive Engineers and Brotherhood of Railroad Trainmen (Ind.).	Wage increase of 18½ cents an hour	350,000
May 28	1	City of Rochester, N. Y	AFL and CIO Unions—general sympathy strike.	City officials issued statement that municipal employees might join any union of their choice which did not claim the right to strike against the public.	20,000
May 31	8	Anthracite Mines, Pa	United Mine Workers (AFL)	Wage increase of 18½ cents an hour and welfare fund established based upon 5-cents a ton levy on each ton produced for use or sale.	75,000
June 3	2	Association of General Contractors of America, Cincinnati, Ohio.	Hod Carriers, Building and Common Laborers (AFL).	Wage increase of 15 cents an hour	10,000
June 27	5	Railway Express Co., New York City and Hudson County, N. J.	Railway and Steamship Clerks (AFL)	Rules governing seniority and work assignments revised.	12,000
July 1	2	Motion Picture Studios, Los Angeles (Hollywood), Calif.	Conference of Studio Unions (Comprised primarily of AFL craft affiliates).	Contract effective through Dec. 31, 1947, granted increase of 25 percent in basic wage scales with provision for renegotiations of wages if area living costs, as measured by the Bureau of Labor Statistics, increase by 5 percent or more between July 1, 1946, and Jan. 1, 1947. It was stipulated that there would be a 36-hour week for "off production" workers who were previously on a day-to-day basis and that they would be given at least a week's work each time they were hired.	14,000
July 10	4	New York City and other Atlantic ports	Seafarers' International Union (AFL) and its affiliated Sailors Union of the Pacific (supported by other AFL unions). National Maritime Union (CIO).	Piers servicing CIO-manned ships picketed by AFL unions in protest against CIO boycott of AFL-manned ships on West Coast. Pickets withdrawn on East Coast when SIU and SUP accepted a Government proposal for arbitration of West Coast dispute.	11,500

July 31	(5)	Waterfront Employers' Association, San Francisco, Long Beach, and Los Angeles, Calif.	International Longshoremen's Union (CIO).	Stoppage occurred as result of the Waterfront Employers' Association's refusal to recognize the International Longshoremen's and Warehousemen's Union as bargaining agent for the longshore "walking bosses" without NLRB certification. Work resumed following announcement by NLRB that it would open oral arguments Aug. 2 on the foremen's demands for certification of the ILWU as their bargaining agent.	12,000
Aug. 12	11	Building and Construction Industry, Buffalo, N. Y.	Allied Building Trades Council (AFL)	Unions protested order of National Wage Adjustment Board to return to wage levels prevailing before July 1, thereby reducing 25-cent hourly wage increase previously denied by Board and put into effect in July during temporary expiration of wage stabilization controls. Work resumed on Board's promise to reconsider case.	18,000
Aug. 14	1	General Motors Corp.—Fisher Body Plant, Truck and Coach Division, and Pontiac Motor Division.	United Automobile Workers (CIO)	Work resumed after 1-day demonstration by war veterans who demanded vacation pay for 1946.	11,000
Aug. 29	2	Commercial and Industrial Construction, Cuyahoga, Goauga, and Lake Counties, Ohio.	Building Trades (AFL)	Building-trades employees halted work in protest against the action of the carpenters who left jobs in commercial and industrial building, objecting to decision of National Wage Adjustment Board approving rate of $1.87½ instead of $1.90 an hour. Building-trades employees terminated their stoppage when carpenters resumed work on instructions from their international union.	24,000
Sept. 1	(6)	Trucking companies, New York City area and N. J.	Brotherhood of Teamsters (AFL)	Settlements reached with some employers, led by H. C. Bohack Co., Inc., on Sept. 17, providing for $7.40 weekly raise with a 40 instead of 44-hour week. Settlements reached with practically all other employers on generally similar basis during following 6 weeks.	31,000
Sept. 5	17	Maritime Industry, unlicensed personnel—Atlantic, Gulf, and Pacific Coast ports.	Seafarers' International Union (AFL) and its affiliated Sailors Union of the Pacific (supported by other AFL and CIO unions).	Union protested against National Wage Stabilization Board disapproval of negotiated increases of $27.50 and $22.50 a month for East and West Coast seamen, respectively, which exceeded previously approved increases of $17.50 for same classes of personnel. AFL stoppage terminated when Government amended wage regulations, thus approving bargained rates.	132,000
			Upon settlement of above dispute on Sept. 12, the National Maritime Union (CIO), Marine Cooks and Stewards (CIO), and Marine Firemen, Oilers, Watertenders and Wipers Association (Ind.) renewed demands for wage adjustments equal to those obtained by AFL maritime workers.	Arbitration (Fly) award of Sept. 19 raised rates of substantially all NMU personnel to those paid AFL unions. Award of Sept. 24 extended parity increases to Marine Cooks and Stewards. Maritime Commission instructed West Coast operators to apply principles of the award to Government-owned vessels. Parity increases subsequently applied to Pacific Coast Marine Firemen and Oilers.	
		See footnotes at end of table.			

Table 11.—*Work stoppages beginning in 1946 in which 10,000 or more workers were involved*—Continued

Beginning date	Approximate duration (calendar days)	Establishment(s) and location	Union(s) involved	Major terms of settlement	Approximate number of workers involved
Sept. 11	1	Hudson Motor Car Co., Detroit, Mich.	United Automobile Workers (CIO)	Plant inspectors demanded new job classification involving increase of 5 cents an hour. Work resumed with no change in conditions.	12,000
Oct. 1	(7)	Maritime Industry, licensed personnel—Atlantic, Gulf, and Pacific Coast ports; longshoremen on Pacific Coast.	Marine Engineers' Beneficial Association (CIO), Masters, Mates & Pilots (AFL), and International Longshoremen's Union (CIO).	Strike of MEBA and MMP licensed personnel on East and Gulf Coasts terminated by end of October. Settlement provided 15-percent increase in monthly rate and 35-cent increase in overtime rate, to $1.60 an hour. Union preference in hiring secured by MEBA and for MMP except certain groups of captains. Maintenance of membership secured by MEBA and MMP exclusive of captains. West Coast stoppage terminated on Nov. 23. MEBA and MMP agreements provided for 15-percent increase in monthly rate, overtime of $1.60 an hour, and continuance of sole bargaining rights. Longshoremen secured an 11-percent wage increase.	142,000
Oct. 21	26	Transcontinental & Western Air, Inc. (Trans World Airline).	Air Line Pilots Association (AFL)	Parties agreed to submit wage and other issues to arbitration.	13,000
Nov. 21	17	Bituminous Coal Mines, industry-wide [8]	United Mine Workers (AFL)	Work resumed on basis of Krug-Lewis agreement of May 29, 1946, following court action and back-to-work order of union president.	[8] 335,000
Dec. 3	2	General strike, Oakland, Calif.	Retail Clerk's Int'l Association (AFL) in original dispute. AFL unions participated in general sympathy strike.	Strike terminated upon promise of city officials not to use police to guard "professional strikebreakers" and to refrain from "taking sides" in labor-management disputes.	50,000

---

[1] General Motors Corp. (Electrical Division) settled on Feb. 9, General Electric Co. on Mar. 14, and Westinghouse Electric & Manufacturing Co. on May 10.

[2] Settlement on Feb. 15 with U. S. Steel Corp., followed by agreements with other large basic steel companies within 4 days, resulted in the return to work of approximately 450,000 employees. Virtually all the remaining 300,000 workers went back to their jobs at various dates during the next 2 months as additional settlements were reached.

[3] Chase Brass Co. settled on Apr. 6 and American Brass Co. on May 19.

[4] Duration of stoppages at various plants as follows: La Porte, Ind., Mar. 14-Oct. 12; Norwood, Ohio, Mar. 19-Sept. 28; Pittsburgh, Pa., Mar. 22-Sept. 16; Springfield, Ill., Apr. 16-Sept. 18; Hyde Park (Boston), Mass., Apr. 30-Dec. 8; La Crosse, Wis., Apr. 30-Oct. 24; West Allis, Wis., Apr. 30, 1946-Mar. 23, 1947.

[5] Majority of employees resumed work Aug. 1; some idleness continued through Aug. 1 in Los Angeles area.

[6] Some settlements were reached on Sept. 17. Virtually all other employers settled in the following 6 weeks.

[7] MEBA and MMP on East and Gulf Coasts signed agreements on Oct. 22 and Oct. 26, respectively. West Coast stoppage continued until Nov. 23.

[8] This figure does not include some 7,500 anthracite miners who were idle for 2 days during this period following an erroneous report that their president had been jailed.

METHODS OF TERMINATING WORK STOPPAGES

Despite the postwar emphasis upon a return to "free" collective bargaining, the assistance of Government agencies in terminating work stoppages was required in slightly more than half of the disputes ending in 1946 (table 12). These controversies, in the settlement of which Government conciliators and mediators participated, involved about three-fourths of all the workers. By contrast, 1 stoppage out of every 3 was settled directly by the parties affected without any outside assistance.

The United States Conciliation Service closed 3,435 work stoppage cases during 1946, a total greater than the number of work stoppages reported settled with the assistance of Government agencies (table 12). The Bureau of Labor Statistics includes in a single stoppage all employers involved in a controversy or issue that simultaneously affects a group of employers jointly, or the industry as a whole, irrespective of the number of individual employers or the number of local unions involved, and irrespective of the number of separate contract negotiations which may have taken place before the work stoppage was settled. The Conciliation Service counts as a separate work stoppage case each such negotiation to which a conciliator is assigned to aid the parties in their efforts to reach an agreement.

Frequently, in disputes involving a number of employers, agreements are reached through a series of separate negotiations between employers and local unions which result in separate and sometimes different contracts. The 1946 industry-wide steel strike involving over 1,200 separate employers was counted by the Bureau as a single stoppage. The complete termination of this work stoppage, however, required several months of separate negotiations between employers and local unions in widely scattered areas of the country. The Conciliation Service in all of its 7 regions participated in more than 140 negotiations between employers and local unions of the United Steelworkers. The Conciliation Service therefore recorded over 140 cases in this situation. The same circumstances existed, in varying degrees, in a number of other multiplant or multiemployer stoppages that occurred in 1946 where separate labor-management negotiations took place.

The activities of the Federal Government in providing aid in conciliating labor-management disputes were supplemented in many instances by the work of similar State agencies. Various municipalities also manifested an increasing interest in developing machinery to solve their local labor-management controversies, and in this connection the Toledo (Ohio) Labor-Management Citizens-Committee plan for industrial peace received widespread attention. Other municipalities, such as New York, established new or additional machinery to facilitate the peaceful adjustment of labor disputes.

About 1 out of every 9 stoppages ended without any formal settlement. Most of these cases involved relatively small groups of workers. In a few instances (36) the employer was reported to have discontinued business allegedly because of labor difficulties.

Government seizure of plants or an industry because of a labor-management controversy occurred in 5 instances in 1946. These cases involved the large meat-packing companies, New York harbor tugboats, bituminous-coal mines, and the railroads on two separate occasions, one of which involved virtually all of the Nation's railroads and the other a single industrial carrier. This was in marked contrast with the two preceding years, when seizure by the Federal Government was resorted to on 24 occasions in 1945 and 19 in 1944.

TABLE 12.—*Methods of terminating work stoppages ending in 1946*

Method of termination	Stoppages		Workers involved		Man-days idle	
	Number	Percent of total	Number	Percent of total	Number	Percent of total

[1] Less than a tenth of 1 percent.

RESULTS OF WORK STOPPAGES

Tables 13, 14, and 15 present data indicating the extent of success or failure of the stoppages ending in 1946 insofar as such results can be ascertained or measured. In four out of five stoppages the issues were resolved or disposed of at the time the stoppages terminated. In about 40 percent of the stoppages the workers involved obtained substantially what they had demanded; in 22 percent they settled on a compromise basis, obtaining part of their demands; in 13 percent they gained little or nothing; and in 18 percent the issues were to be negotiated further and settled after termination of the stoppages. Wage strikes were the most successful from the workers' viewpoint. The issues in most of the smaller stoppages and the extremely large strikes were definitely settled or disposed of when the stoppages terminated whereas about a fourth of the stoppages involving 500 and up to 10,000 workers were terminated with the issues to be further negotiated or settled later.

TABLE 13.—*Results of work stoppages ending in 1946*

Result	Stoppages		Workers involved		Man-days idle	
	Number	Percent of total	Number	Percent of total	Number	Percent of total
Total	4, 990	100. 0	4, 940, 000	100. 0	124, 000, 000	100. 0

STOPPAGES, BY UNION AFFILIATION

Slightly more than half of all work stoppages ending in 1946 involved affiliates of the American Federation of Labor (table 16). Unions affiliated with the Congress of Industrial Organizations participated in a third of the year's stoppages. Reflecting the type of organization characteristic of CIO unions, somewhat more workers were involved in CIO than AFL stoppages, and the resultant idleness, owing principally to a relatively few large strikes, was substantially greater for the CIO than for the AFL.

In a small number of controversies (2.4 percent), two or more unions of different affiliation—AFL, CIO, or independent (unaffiliated)—were rival participants. Most of these cases centered about organizational or jurisdictional claims. In a few cases (0.6 percent), two or more different union groups participated jointly in strike action. Such cooperative relationships between AFL and CIO, or between either or both of these groups and one or more unaffiliated unions, prevailed in some of the maritime controversies and in various sympathy demonstrations.

About 1 out of every 16 stoppages ending in 1946 involved an independent labor organization, i. e., a union not affiliated with a larger federated group such as the AFL or CIO. The number of strikes occurring in this group has fluctuated considerably in recent years with the shifting status of such large unions as the United Mine Workers and the International Association of Machinists. More than half of the workers involved in the unaffiliated group of unions were affected by stoppages involving the railroad brotherhoods, principally the Nation-wide rail strike of May 1946.

Single-firm unions—organizations confined to employees of one company—participated in 18 relatively small stoppages. By contrast, there were 97 strikes in which no union was identified as a party to the controversy.

Table 16.—*Work stoppages ending in 1946, by affiliation of labor organizations involved*

Labor organizations involved	Stoppages		Workers involved		Man-days idle	
	Number	Percent of total	Number	Percent of total	Number	Percent of total
All affiliations	4,990	100.0	4,940,000	100.0	124,000,000	100.0

No unions	97	1.9	13,500	.3	54,700	(1)
Affiliation not reported	12	.2	930	(1)	4,120	(1)

[1] Less than a tenth of 1 percent.

ESTABLISHMENTS INVOLVED

As in previous years, by far the largest number of stoppages ending n 1946 (74 percent) involved but 1 mill, factory, plant, or establishnent (table 17). Almost 1 million workers were directly affected by hese disputes. On the other hand, the relatively small proportion (7.2 percent) of stoppages involving 11 or more establishments was nore than double that recorded for 1945 and accounted for 70 percent of all workers and 75 percent of the year's time loss. Included in the atter totals were, of course, the large multiplant and multiemployer toppages which dominated the pattern of labor-management stopages in 1946.

Table 17.—*Work stoppages ending in 1946, by number of establishments involved*

Number of establishments involved [1]	Stoppages		Workers involved		Man-days idle	
	Number	Percent of total	Number	Percent of total	Number	Percent of total
All establishments	4,990	100.0	4,940,000	100.0	124,000,000	100.0
establishment	3,698	74.0	998,000	20.2	17,700,000	14.3
to 5 establishments	756	15.2	407,000	8.2	11,000,000	8.9
to 10 establishments	178	3.6	92,000	1.9	2,410,000	1.9
1 establishments and over	358	7.2	3,440,000	69.7	92,700,000	74.9

[1] An establishment, for purposes of this table, is defined as a single physical work place—a factory, mine, onstruction job, etc. Some of the year's stoppages involved several establishments of a single employer; thers involved establishments of different employers.

Work Stoppages in Each State, By Industry Group

Thirty-four of the 48 States had 25 or more work stoppages during 1946. In table 18 the stoppages in each of these 34 States are classified according to industry groups.

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., July 28, 1947.

The Secretary of Labor:

I have the honor to transmit herewith a study on labor requirements in the production of certain types of nonrigid home insulation. This study is the fifth in a series conducted by the Bureau's Construction Statistics Division to determine the amount of labor needed to produce the more important construction materials; it was prepared by Carl R. Taylor and Benjamin Levine, under the direction of Thomas M. Flanagan. The Bureau wishes to acknowledge the cooperation of the companies which provided data for the survey, and of their trade associations.

Ewan Clague, *Commisioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Labor Requirements to Produce Home Insulation

Mineral Wool, Cotton and Expanded Vermiculite

Characteristics of Industry's Products

This study is the fifth in a series[1] which the Bureau of Labor Sta-istics has been conducting to determine the amount of labor needed o produce the more important construction materials for the present iousing program or for other construction activity.

The present survey analyzes the amount of labor required to produce 3 important types of nonrigid home insulation material: mineral vool, cotton, and expanded vermiculite. It describes the processes involved in the manufacture of these materials, and analyzes the man-iours required per unit of product at each production level, from nining or growing the raw material to transporting the finished roduct.

The use of insulation in new residential construction has increased apidly in recent years and, during the war, insulation of existing uildings became especially important as a fuel-conservation measure. Savings in fuel costs are estimated at around 30 percent for insulated, s compared with uninsulated homes.[2]

---

[1] This survey, covering three important nonrigid insulation materials, is the first of two tudies of the labor required to produce home insulation. The second will cover labor equirements for fiber insulating board, a rigid type of insulation material. Building aterials for which results will be reported in future articles include hardwood and ardwood flooring, and plumbing and heating supplies. Previous studies covered labor equirements in cement production, summarized in the September 1946 Monthly Labor eview (p. 355); labor requirements in the production and distribution of concrete asonry products and concrete pipe, summarized in the November 1946 Monthly Labor eview (p. 681); in southern pine lumber production, summarized in the December 1946 onthly Labor Review (p. 941); and in softwood plywood production, summarized in he January 1947 Monthly Labor Review (p. 67).

[2] Bowles, Oliver; Home Insulation With Mineral Products, in Information Circular umber 7388 (U. S. Department of Interior), October 1946, p. 7.

Nonrigid insulating materials usually consist of interlaced wool-like fibers or hollow or stratified granules, providing millions of minute spaces in which dead air is enclosed and, thus, having especially low heat conductivity. Their function is to reduce the transfer of heat from one side of a wall, ceiling, or roof to the other, irrespective of the side on which the heat is generated. In winter, the use of insulation reduces the escape of heat from the inside of a dwelling, maintaining a higher indoor temperature with decreased fuel consumption. In summer, the reverse occurs, and insulation reduces the penetration of the heat of the sun through walls and ceilings to the interior of the house.

There are many types of insulating materials, but in general they fall into two categories: the rigid, such as fiber board, used in new construction or in remodeling in place of lathing or wall sheathing; and the nonrigid, varieties of which are discussed in this report. Nonrigid insulation has no structural value, but is placed in the hollow spaces of walls, between floor joists, or between roof and rafters. It is used effectively to insulate existing buildings and is also installed in new construction. Most types are fire resistant or flameproofed, and it has been found that even in frame dwellings the spread of fires is hindered by the use of insulation in ceiling and roof, as well as by filling the hollow spaces of walls and partitions.

Of the three types of nonrigid insulation covered in this survey, mineral wool is the most important in terms of tons produced and sold each year. (See table 1.) The processed mineral wool is a fibrous, intermeshing material, resembling natural wool. It is composed principally of silicates of calcium and aluminum and is produced from three principal types of raw material: natural rock or combinations of various natural minerals or rocks, such as limestone and shale; iron, copper, or lead blast-furnace slag; and such glass materials as silica sand, soda ash, and limestone. The mineral wool is named rock wool, slag wool, or glass wool, according to the raw materials from which it is made. Mineral wool is sold commercially for home insulation in three forms: loose, granulated, or as batts and blankets.

Loose wool is the initial product after the first processing operation and it is from loose wool that the other mineral wool products are prepared. Loose wool is sold by the bag and installed by hand.

Granulated wool is by far the most widely used of the three forms. It is the only product from which the shot, or grains of slag have been removed. Because the granules are formed into small pellets and can be blown between the framing of buildings with an air hose, granulated wool is used chiefly for the insulation of existing buildings. Like loose wool, it is usually sold by the bag.

Blankets and batts of mineral wool have been fashioned into soft flexible quilts, usually surfaced on one or both sides by specially eated vapor-proof paper. Batts are similar to blankets except that ey are usually smaller in size. Batt and blanket wool are sold by e roll or carton and installed by hand.

Processed flameproofed cotton is a comparatively new product, dat- g from 1940. It is sold only in the batt or blanket form, by the roll r carton. Expanded vermiculite, granular in form, is marketed by e bag, as a fill type of home insulation material. It is prepared om vermiculite ore, which closely resembles mica in appearance and characterized by its extraordinary quality of expansion when heated.

ABLE 1.—*Estimated production of mineral wool, cotton, and expanded vermiculite home insulation, 1942 and 1946*

Type of insulation	Tons produced	
	1942	1946
Total (all types)	411,450	681,295
Mineral wool [1]	377,603	631,611
Loose wool	58,586	56,213
Granulated wool	183,107	408,021
Blanket or batt wool	135,910	167,377
Cotton [2]	873	9,050
Expanded vermiculite [3]	32,974	40,634

[1] For 1942 production figures, see Minerals Yearbook, 1943, p. 1583. Production figures for 1946 for all ineral wool of the types shown are based on the production estimate for 1945 furnished the U. S. Bureau Mines by the Mineral Wool Association, and increased by 12 percent—the Bureau of Mines estimate the rise in mineral wool production in 1946 compared with 1945. Production in 1946 was distributed by pe of mineral wool in the same ratio as found in the production of the plants covered in the Bureau of bor Statistics' survey during 1946.

[2] For 1942 production figures, see E. H. Omohundro and N. B. Salant, Cotton Insulation. Washington, C., U. S. Department of Agriculture, et al., December 1944, p. 2. The 1946 figure is an estimate fur- shed by the U. S. Department of Agriculture. Production of cotton insulation not covered in the De- rtment of Agriculture incentive program is excluded, but this is believed to be very small.

[3] For 1942 production figure, see Minerals Yearbook, 1943 p. 1588. It is estimated that 60 percent of e total production is used in home insulation. The 1946 figure is an estimate provided by the U. S. ureau of Mines.

Scope and Method of Survey

The mineral wool survey covers 10 plants representing about one- ird of 1946 production. The studies of labor requirements to pro- uce flameproofed cotton and expanded vermiculite were made by nalyzing the records of four and six plants, respectively, accounting r something over 50 percent of 1946 production in each of these dustries.

The companies and plants to be included in the survey were selected fter consultation with appropriate trade associations, government fficials, and industry members. Small, medium, and large plants in ich branch of the insulation field, were selected in approximately the me ratio in which they are distributed in the industry. Figures on nit man-hours for each plant were weighted by the plant's estimated 946 production in order to arrive at estimated average man-hours re- uired per unit of output in each of the three insulation industries rveyed.

Data were collected in the latter part of 1946 and, in each case, a period was selected for survey that plant officials considered typical of their 1946 operations. Field representatives of the Bureau of Labor Statistics, working with plant officials, derived the information on total man-hours spent on each manufacturing process and in administration, from plant records. Man-hour requirements were estimated for extracting and transporting the raw materials, for power, and for transporting the finished product to local dealers and users on the basis of the following: (1) plant information on quantities consumed and produced; (2) labor requirements information obtained from various sources, including the extraction and utility industries represented; and (3) earlier surveys of the Bureau of Labor Statistics. No attempt has been made in this study to include the man-hours expended by distributors, jobbers, or retailers in selling the finished product.

Summary of Man-Hour Requirements

An average of 9.1 man-hours was required in 1946 to manufacture a ton of mineral wool home insulation, according to the Bureau's survey. Loose wool, because of the simplicity of its manufacture, required only 6.7 man-hours per ton to produce in the factory; granulated wool required somewhat more labor (8.2 man-hours) as a result of an added processing step, and batt or blanket wool still more (12.2 man-hours) reflecting primarily the process of fashioning the wool into the blanket-type product and affixing the vapor-proof backing. About 5.6 man-hours may be added on the average for producing and transporting the raw materials, fuel, and other products used in making mineral wool, and for transporting the finished wool to dealers.

Flameproofed cotton insulation is measured by the thousand square feet. The Bureau's survey shows that while only 4.2 man-hours were required to produce a thousand square feet of cotton insulation in the plant in 1946, 85.8 per thousand square feet were needed for the outside activities of making the cotton and other materials available, and shipping the finished product. Of the 85.8 man-hours, 84 were required just for growing and preparing the cotton for delivery to the insulation plant, according to estimates of the Department of Agriculture.

In the case of expanded vermiculite, also, man-hour requirements for processing are not as high as those for producing and transporting the raw materials, fuel, and other products used and for shipping the finished insulation. Expanded vermiculite is measured by the thousand cubic feet. An average of 25.2 man-hours was found to be needed in 1946 to manufacture a thousand cubic feet of expanded vermiculite, compared with 35.9 man-hours for the out-of-plant activities, making a total of 61.1 man-hours per thousand cubic feet from mine to dealer. A large part of the man-hour requirements for producing vermiculite insulation (19.4 man-hours) was expended in transporting the vermiculite ore from the mines, which are situated in a very few States, to the scattered processing plants. Since the cubic footage of vermiculite expands considerably during processing, the manufacturing plants are located near distributing centers and often quite distant from the source of raw materials, to save transportation costs.

It is clear from the above discussion that the production man-hour requirements vary considerably per unit of product between the three home-insulation materials discussed in this report, when each industry's customary unit of measurement is used. Using a common unit of measurement with reference to the use to which the material is put (i. e., the amount of insulation material 3 inches thick required to cover a thousand square feet of space), the Bureau has computed roughly that labor requirements in the factory vary little by type of product, ranging from a little over 4 to something over 6 man-hours per unit. Variations are much greater when nonmanufacturing labor needs are considered, because of the differences in raw materials used and in transportation problems, as described briefly above.

Mineral Wool

HISTORY AND ANNUAL PRODUCTION

Production of mineral or rock wool was first reported in 1840 in Wales.[3] Commercial production in this country is believed to have tarted at Alexandria, Ind., in 1897 when C. C. Hall established a plant for the production of rock wool to utilize the slag produced as waste in the operation of a steel plant. Annual production in 1900 was estimated to be 6,002 short tons, increasing to 11,626 tons in 1909 and dropping to 7,514 tons in 1911. Production in 1928 was estimated at around 50,000 tons [4] increasing to 500,000 tons in 1936 and decreasing to approximately 400,000 tons in 1938.[5]

The centennial celebration of the mineral wool industry was held in Chicago in 1940.[6] Only estimates rather than actual production figures are available for most other years prior to 1942, although the Bureau of Census has released some data on dollar value of mineral wool produced for certain earlier years. Recent data on mineral wool production are shown in table 2.

1945 [3]	563,939	78,952	406,036	78,951
1946 [4]	631,611	56,213	408,021	167,377

[1] Minerals Yearbook 1943, p. 1583.

[2] Op. cit. 1944, p. 1541.

[3] Estimate for the total was provided to the U. S. Bureau of Mines by the Mineral Wool Association. Production by type of mineral wool was estimated by the Bureau of Labor Statistics, using the same ratio to the total as in 1944.

[4] Figure for the total was based on the production estimate for 1945, increased by 12 percent—the Bureau of Mines estimate of the rise in mineral wool production in 1946 compared with 1945. Production by type of mineral wool was distributed in the same ratio as found in the production of the plants covered in the Bureau of Labor Statistics' survey during 1946.

PRODUCTION PROCESS

Though variations in the technique of manufacturing mineral wool occur from plant to plant, the process may be described generally as follows: Different combinations of coke with slag, rock, shale, dolomite or limestone, among others, are fed into a cupola—a furnace used in melting minerals. Automatic scales are usually used to weigh the amount of each raw material to be put into each charge. The charge is heated to a melting temperature of from 2,500° F. to around 3,500° F. and is then drawn off from the cupola in a thin stream. The stream of melted slag, about the size of a lead pencil, drops from a few inches to something over a foot. It is then intercepted by a blast of steam which catches it and blows it into the adjacent blowing or wool room. The blowing temperature is usually 300 to 500° F. lower than the melting temperature.

As the slag droplets are traveling at high speed through the air, each tails out into fibers or strands. The minute amount of each droplet of slag that does not strand out or form fibers, but remains as a tiny ball or knot of slag, is called "shot." A single piece of shot is about the size of a grain of sand. As shot has no insulation value, its elimination in the production process is highly desirable, and the degree of efficiency of the blowing process is in part measured by the small shot content of the loose wool. To reduce the dust, an oil spray is mixed with the steam, or strikes the wool after it has been blown a few inches.

The blowing rooms are enclosed and are narrow and high and usually from 20 to 50 feet in length. A conveyer belt ordinarily forms the floor and removes the blown wool from the wool room through a small opening. In some plants the wool is removed by hand. At this point the processing of loose wool is completed and it may be bagged and shipped.

In the case of granulated wool, the conveyer may move the wool out of the wool room onto a belt through a series of grinders that break up the fibers. The wool then passes into a rotary screen which causes the formation of small round pellets or nodules, producing granulated, often called nodulated wool. The shot drops through the screening to be returned to the furnace and remelted. There is about a 17-percent loss in pounds between the raw slag used and the loose wool produced. If the loose wool is further processed into granulated wool, an additional loss of 25 percent is incurred, making an average loss of about 42 percent in processing granulated wool.

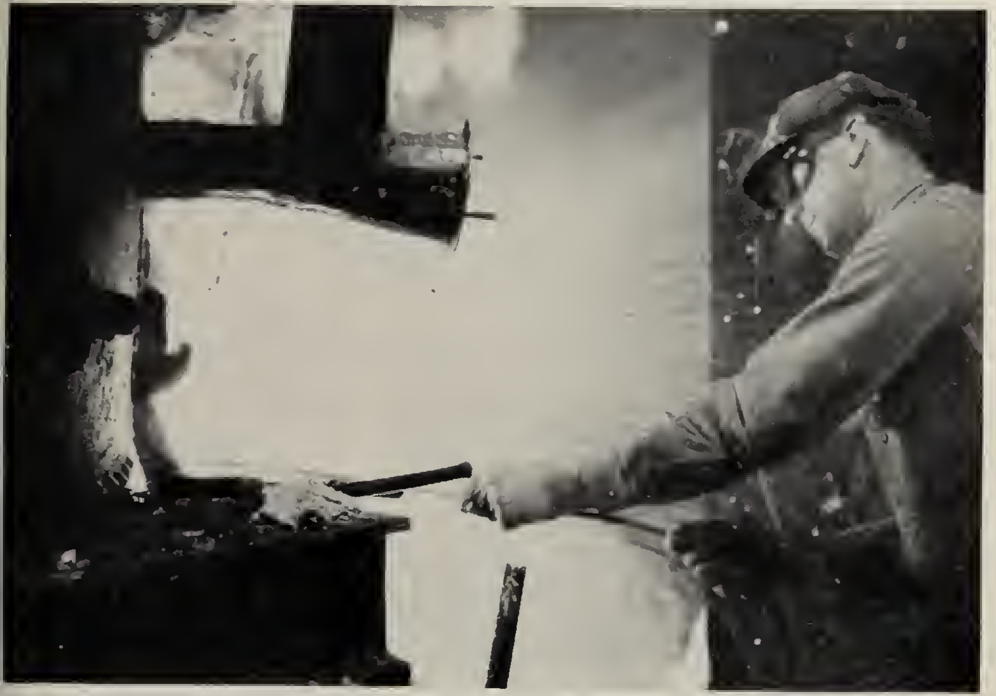

FIGURE 1. Blowing mineral wool: As the molten slag leaves the cupola in a thin stream, it is intercepted by a blast of steam and blown into the wool room, thus forming loose mineral wool.

To make batt or blanket wool, the loose wool is removed from the wool room, usually on a conveyer belt, and sprayed with resin or some other binder. It then passes through rollers which compress the wool with the binder and set it into a continuous mineral wool blanket. Following this, the blanket passes through ovens which complete the process of binding and setting the blanket in permanent form. Blankets are made from 1 to 4 inches thick to suit various insulation purposes. The conveyer moves the newly formed blanket along to the point where the moisture-proof vapor-barrier paper is added as backing, though batt or blanket wool is sometimes made without paper backing. The mineral blanket is then cut and trimmed automatically to batt or blanket sizes, automatically rolled, and then hand packed for shipment. The wool clippings from the trimming operation are salvaged and made into granulated wool.

In some of the larger plants, there is a separate production line for each type of wool, but in smaller plants one cupola produces the loose wool used to make granulated and batt or blanket wool.

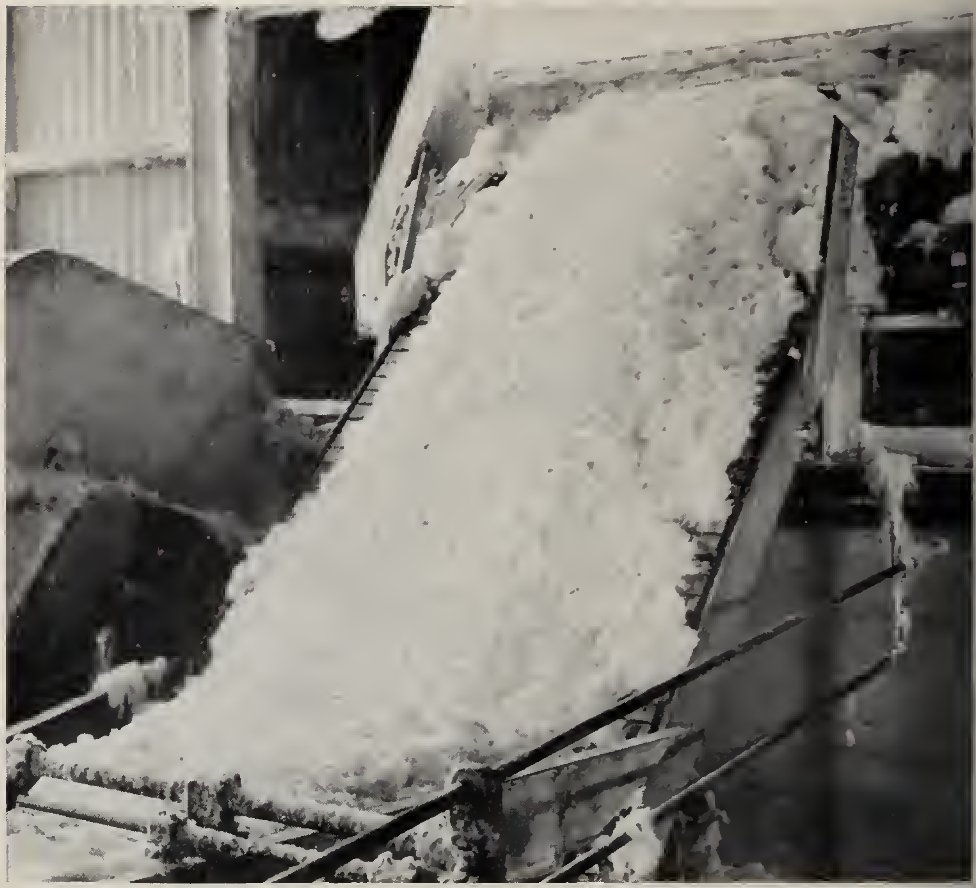

FIGURE 2. Loose mineral wool: An endless belt conveys the blown wool from the wool room for bagging or further processing into granulated or batt and blanket wool.

LABOR REQUIREMENTS IN MANUFACTURING

The labor requirements to manufacture a ton of mineral wool for all processes combined have already been quoted (p. 6). Figures showing detail by department or process are presented in table 3.

It will be noted that the processing of granulated wool requires more labor than loose wool chiefly in the maintenance department, as a result of the additional machinery required for nodulating or granulating the wool, removing the shot, and then bagging the wool automatically.

Also, more labor is required to make granulated wool than loose wool, because of the loss or waste in raw materials caused by removal of the shot. This necessitates handling and heating more raw material to produce a ton of the granulated mineral-wool product.

While granulated wool is bagged automatically, loose wool must be bagged by hand, as the fibers tend to cling together to form large masses or lumps. Man-hours required for packing loose wool, in fact, exceed those for processing. In contrast, the pellets of granulated wool are easily bagged by machine.

Most of the additional labor required to produce batt or blanket wool as compared with granulated wool is employed in the manufacturing and packing department where additional machine operations require a larger number of machine tenders. In addition, batt or blanket wool is hand packed in contrast with the automatic bagging of granulated wool. Machine maintenance and labor supervision also are more extensive in making batts or blankets.

TABLE 3.—*Man-hour requirements per ton to manufacture mineral wool home insulation in 1946, by type of mineral wool product*

Major department or process	Average man-hours required per ton of mineral wool for—			
	All types (weighted average)	Loose wool	Granulated wool	Batt or blanket wool
All departments	9.1	6.7	8.2	12.2
Handling raw materials	.3	.1	.3	.4
Cupola	2.4	2.2	2.4	2.4
Manufacturing and packing	3.4	2.5	2.5	5.6
Loading and shipping	.7	.7	.8	.7
Administration, clerical, and sales	.6	.3	.6	.7
Maintenance	1.3	.6	1.3	1.9
Superintendent and foreman	.4	.3	.3	.5

A relationship can be seen between production level and average man-hour requirements per ton in the mineral wool plants surveyed. The greater the plant's production, the lower the average man-hour requirements to produce each ton. The relationship appears to affect practically every processing department, as shown in table 4.

TABLE 4.—*Average labor requirements per ton of mineral wool produced in 10 plants in 1946, by estimated monthly production and by major department*

Major department	Man-hours required per ton in plants with monthly production of—		
	Less than 1,000 tons	1,000 to 2,000 tons	More than 2,000 tons
All departments	17.6	10.8	8.3
Handling raw materials	.6	.5	.2
Cupola	4.1	2.7	2.2
Manufacturing and packing	4.7	3.9	3.1
Loading and shipping	2.1	1.3	.6
Administration, clerical, and sales	1.5	.7	.5
Maintenance	2.2	1.2	1.5
Superintendent and foreman	2.4	.5	.2

OUTSIDE LABOR REQUIREMENTS

To follow the employment needs for producing mineral wool from mine to dealer, it was necessary to study how much labor was required to produce and transport the raw materials, fuel, and other major products needed to make this type of home insulation and it was necessary to compute, also, the labor required to transport the finished product from the plant. Estimates of these labor needs are, at most, approximate and could be prepared only for loose wool.

Labor needs for all these activities averaged 5.6 man-hours per ton of loose wool produced. When added to manufacturing man-hours (6.7 per ton), a total of 12.3 man-hours per ton is derived for the labor needs from extraction of the raw materials to delivery of the finished product. The nonmanufacturing labor requirements undoubtedly vary somewhat for the granulated and batt or blanket types as compared with loose wool. On the average, however, it is safe to say that about 15 man-hours (9.1 for manufacturing and 5.6 to produce the material used, etc.) are required to produce one ton of all type mineral wool home insulation, from mine or slag pile to dealer.

The method by which these totals were derived may be described briefly as follows: An average cupola charge contains about 2,400 pounds of blast furnace slag, 40 pounds of gravel, and 400 pounds of coke. It is estimated from information of the National Slag Association and previous studies of the Bureau of Labor Statistics,[7] that an average of 1.3 man-hours is needed to produce these raw materials at their source, distributed as follows: 0.24 man-hour for the slag, 0.01 for the gravel, and 1.07 for the coke. Using earlier Bureau figures on labor needs in transporting raw materials to the site of manufacture,[8] it is estimated that a total of 0.5 man-hour was required to deliver the raw materials to the mineral wool plants—0.26 man-hour for the slag, 0.01 for the gravel, and 0.20 for the coke.

The fuel used at the plant—about 280 lbs. of coal and 39 kw.-hr. of electricity per ton of loose wool—is estimated to require 0.18 [9] and 0.10 [10] man-hour, respectively, and other materials (principally the

---

57 bags required for a ton of loose wool) about 0.5 man-hour. The transportation of the coal requires 0.21 man-hour, making an approximate total of 1 man-hour for fuel and materials used.

The rail haul of the finished wool is estimated to average 375 miles. requiring 2.8 man-hours per ton of wool transported.[11] An estimated average of 13 tons of mineral wool is carried per car.

Cotton Insulation

Cotton insulation is made from sound, staple, well-cleaned, and firmly matted material. The matting of the individual hollow tubular fibers, each of which contains tiny dead air spaces, forms additional air spaces, thus providing an exceedingly effective natural barrier to the passage of heat.[12]

Cotton insulation was first produced commercially in 1940. It was developed under a United States Department of Agriculture program to create a new outlet for the grades of cotton which are usually surplus. This surplus cotton is made available under incentive payments enabling the producers of cotton insulation to compete successfully with other types of nonrigid home insulation. The acceptance of cotton insulation and the commercial development of the industry since 1940 has been rapid. (See table 5.)

In general, the machinery used to make cotton insulation was adapted from existing types of textile machinery. With the assistance of the Department of Agriculture, methods of flameproofing and mildew-proofing the raw cotton were devised. The firms in the industry now have individual formulas for flameproofing, which they regard as trade secrets.

TABLE 5.—*Production of cotton insulation under the U. S. Department of Agriculture incentive program 1940–46* [1]

Year	Annual production in thousands of pounds
1940	55
1941	769
1942	1, 746
1943	7, 447
1944	8, 544

[12] Cotton Insulation by E. H. Omohundro and N. B. Salant, Washington (U. S. Department of Agriculture), December 1944, p. 5.

PRODUCTION PROCESS

Although the methods and machinery for making cotton insulation vary somewhat from plant to plant, the operations are basically the same in all plants.

The baled raw cotton is unloaded from the freight cars or trucks and stored in a warehouse. As the cotton is needed it is moved by conveyor or hand cart to the beginning of the production line.

The raw cotton is fed into the opener or willower machine which loosens and fluffs it up. The fluffed cotton is then blown through tubes or conveyed on belts to the dipping or soaking vats, which are fed automatically by means of weighing machines. The vats are filled with a combination flameproofing and mildew-proofing chemical.

The cotton moves slowly from one end of the vat to the other, being mechanically agitated all the time so that it is thoroughly soaked with the chemicals. In some cases, the soaking vats are variations of wool washing machines. The soaking process may require as long as 1 hour to complete.

Dry cotton is being continuously fed into one end of the vat while soaked cotton is removed from the other end by a conveyor belt. The belt carries the wet cotton through large rubber squeeze rolls which operate under hydraulic pressure and remove most of the moisture. The conveyor belt continues into a battery of drying ovens where a combination of heat and circulating air thoroughly dries the cotton.

The processed cotton is then fed by blower or conveyor into the blanket-forming machine, sometimes called a batting or spider web machine. Its function is to process the loose cotton into a continuous thin blanket. This is done by a series of carders or combs moving at high speed.

As the cotton leaves the batting machine, it is in the form of a thin blanket. It is then fed layer on layer to the final conveyor belt until the desired thickness of blanket is formed. The blankets are produced in rolls up to 50 feet in length, in widths of 12, 16, 20, and 24 inches, and in thickness from ¾-inch to 4 inches.

The final processes of cutting the cotton blanket to proper width, applying moisture-proof paper backing, and rolling for packing are usually accomplished in one automatic operation. At the end of the batting machine the newly formed blanket is moving along a conveyor belt about 4 feet wide. Slitting knives at the end of the conveyor cut the blanket to the desired 12, 16, 20 or 24-inch width. From under the conveyor belt the special kraft paper, wax coated on one side and asphalt coated on the other, is heated on the asphalt-coated side and fed to the underside of the blanket roll. The entire conveyor moves through a roller which laminates the paper to the blanket and compresses the blanket for packing. At the end of the line the completed blanket is formed automatically into rolls of predetermined size. The rolls are cut automatically to the proper length and are then removed by hand and hand-packed into corrugated boxes. A sample from at least every 2,000 square yards of finished insulation is subjected to certain minimum specification tests as outlined by the Department of Agriculture.

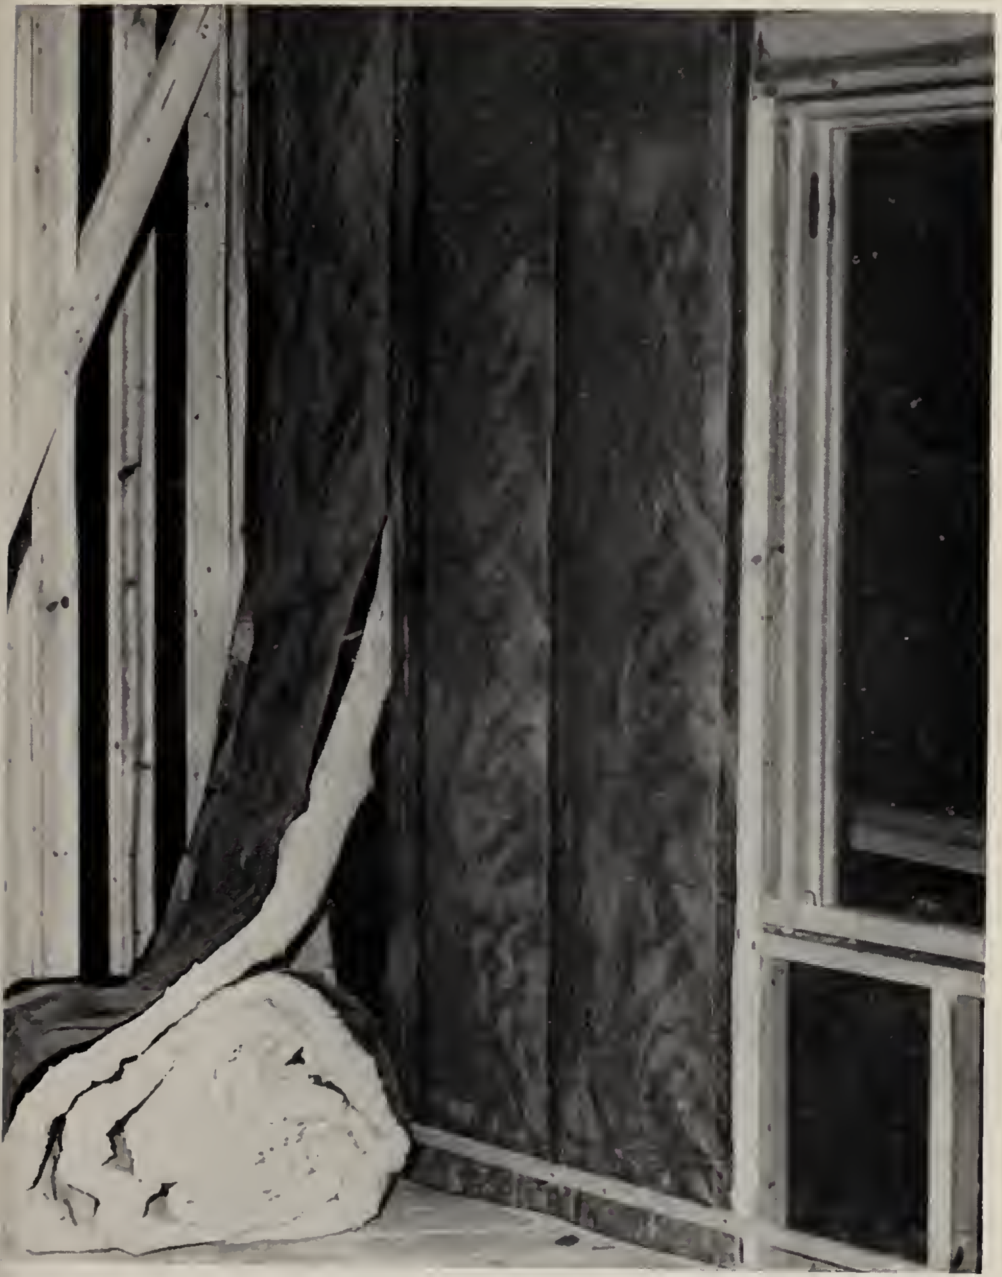

FIGURE 3. Installing cotton insulation: The cotton blankets are installed between the framing structure of the walls in the new house. Other types of batt and blanket insulation are installed in the same manner.

LABOR REQUIREMENTS

Most of the operations performed in processing cotton insulation are automatic. so that manufacturing labor requirements per unit of product are at a minimum. Of the 4.2 man-hours required per 1,000 square feet to process cotton insulation in 1946, half were in the flameproofing and drying, and blanket-forming and cutting departments where most of the processing takes place under the supervision of machine tenders (table 6).

In contrast, the growing, picking, and ginning of the 210 pounds of cotton used per 1,000 square feet is estimated to require 84 man-hours.[13] The material used in producing cotton insulation is lint (virgin) cotton not less than ¾-inch staple and of at least certain minimum quality as required by the Department of Agriculture for participation in the cotton-insulation incentive program. It is shipped to the manufacturers of cotton insulation from various points in the southern cotton belt in 500-pound bales.

TABLE 6.—*Man-hours required to produce and distribute 1,000 square feet of 3-inch-thick cotton insulation in 1946*

Major department or operation	Man-hours per 1,000 square feet of 3″ cotton insulation
Total, all operations	90.0
Production of raw materials	84.5
Transportation of raw materials	.5
Manufacturing	4.2
Handling raw materials	.3
Flameproofing and drying	.7
Blanket forming and cutting	1.7
Packing	.4
Shipping	.5
Administrative, clerical, and sales	.4
Maintenance	.1
Superintendent and foreman	.1
Transportation of finished product	.8

The rail haul from cotton gin to insulation plant is estimated from factory records to average 900 miles for which 0.5 man-hours would be required for the 210 pounds of cotton used per 1,000 square feet of finished product.[14] Another 0.5 man-hours are needed, according to industry sources, to produce the 30.3 pounds of paper used in making 1,000 square feet of insulation. The average rail haul of 300 miles to the plant, as indicated in plant records, is estimated to require only the fractional sum of less than 0.1 man-hours.

Since the amounts and kinds of chemicals used in flameproofing and mildewproofing the cotton are trade secrets, no information on labor requirements could be obtained for these materials, but the labor needed per unit of product is believed to be very small.

---

[13] Based on estimates for 1946 furnished by the Bureau of Agricultural Economics of the U. S. Department of Agriculture.

[14] Based on an average haul of 25 tons of cotton per car. See Monthly Labor Review, October 1937, Labor Requirements in Rail Transportation of Construction Materials.

The average rail haul of the finished insulation was estimated at 500 miles in 1946, requiring 0.8 man-hours per 1,000 feet of insulation, compared with 0.5 man-hours for the average of 900 miles that the raw baled cotton was hauled. The difference is in the fact that 25 tons of baled cotton can be carried per car, as compared with but 5 tons of the finished cotton insulation.

Expanded Vermiculite

When vermiculite ore is subjected to heat of 1,400° F. to 2,000° F., it expands 8 to 15 times its original size and the resulting porous substance has especially high insulating properties. Exfoliation is the term used in the industry to describe the expansion process. Dead air cells within the granules, as well as between the granules of the expanded ore, act as nonconductors of heat, thus giving vermiculite its insulating value. Vermiculite is also incombustible.

It is estimated that about 60 percent of all vermiculite ore mined is used for home insulation. In 1946, this resulted in the production of something over 13 million cubic feet of expanded vermiculite with an estimated value of over 3 million dollars.[15] The exfoliated ore leaves the furnace in various sizes of feather light, resilient pellets ranging from powder or dust to granules about three-quarters of an inch square. The medium granular sizes are used as a loose fill type of home insulation. Other sizes of expanded vermiculite are used to make precast concrete slabs for roof, floor, and wall construction. Because of the light weight of vermiculite, these slabs weigh as little as 25 pounds per cubic foot. Compressed vermiculite wall board also is being manufactured, and in increasing quantities. The powder and smallest granule sizes of the expanded vermiculite are used as concrete or plaster aggregate in place of sand. They are also added to garden soil to make the soil more porous and easy to work.

PROCESS OF MINING AND EXFOLIATING

Vermiculite ore was originally discovered in this country in 1824 near Worcester, Mass., by Thomas H. Webb.[16] At present most of the ore comes from Montana, with a few small mines operating in Colorado, North Carolina, South Carolina, and Wyoming. At least one company has also begun to import ore from South Africa. Raw unexpanded vermiculite ore is composed of minute laminations of mineral ore which have a glossy surface similar to isinglass; as mentioned earlier, the ore is like mica in appearance.

---

[15] Expanded vermiculite was priced at about $75 per ton, f. o. b. plant, in 1946. See U. S. Bureau of Mines Information Circular 7388, October 1946, p. 11.

[16] G. R. Gwinn, Marketing Vermiculite, Bureau of Mines Information Circular 7270, January 1944, p. 1.

Most vermiculite ore comes from open pit mines. A small percentage of gangue[17] or mineral rock containing the ore is mined along with the vermiculite. The raw ore is first crushed into smaller flakes. The oversize gangue is eliminated by a screening operation and the partly crushed vermiculite goes into a rotary or conical type drier. Here it is subjected for a short time to a heat of 200° F. to 300° F. to eliminate part of the free moisture content of the ore. The vermiculite is then graded by screening it into four sizes. Each size is shipped separately in freight cars of 42 to 50 tons capacity. Exfoliating plants order the raw ore by size depending on the ultimate use to which the expanded ore is to be put. This screening, grading. and drying operation is usually done at the mine site, but may be performed at the exfoliation plant when it is located near the mine. While expanded vermiculite has been in continuous commercial use since the early 1920's. production has increased considerably in recent years, and more than tripled between 1940 and 1946. (See table 7.)

TABLE 7.—*Amount and value of screened and cleaned raw vermiculite ore sold or used in the United States, 1935–46* [1]

Year	Short tons	Value	Year	Short tons	Value
1935	7,068	$88,445	1941	23,438	$125,444
1936	16,933	185,787	1942	57,848	319,931
1937	26,556	260,664	1943	46,645	471,595
1938	20,700	192,000	1944	54,116	541,744
1939	21,174	174,587	1945	64,808	648,077
1940	22,299	137,698	1946	71,289	712,890

[1] Data for 1935–42 from U. S. Bureau of Mines Circular 7270, January 1944, p. 6; data for 1943–45 are from U. S. Bureau of Mines Circular 7388, October 1946, p. 11. Figures for 1946 are estimated on the basis of information from the Bureau of Mines that production increased 10 percent over 1945 with the price per ton of vermiculite remaining about the same. (All data are for unexpanded ore.)

When the freight cars of raw ore arrive at the exfoliation plant siding, they are usually unloaded by hand. The ore is hauled and dumped or shovelled into a bucket-type conveyor which lifts it overhead into storage hoppers, from which it moves automatically by conveyor belt to the top of the furnace.

The various plants use different types of furnaces for the exfoliation process. Each is designed to produce the expanded ore by subjecting it to a heat of 1400° F. to 2000° F. for a few seconds. The furnaces are usually heated by forced-air oil burners. Some plants use baffles to delay the fall of the ore through the furnace, while others have the furnace set at an angle so that the ore flows rather than falls through the furnace. As the expanded flakes come out of the bottom of the furnace they are again picked up by conveyor belt or bucket elevator. The flakes, now expanded some 8 to 15 times, are tough and pliable.

---

[17] The mineral or rock material accompanying the ore in a vein.

The expansion process occurs as the result of a minute amount of water between the laminations in the granules of the raw ore, which, when subjected to the heat of the exfoliation furnace, expands and turns to gas, forcing the laminations apart to form expanded vermiculite. Excessive heating drives out all the moisture content and renders the flakes permanently brittle.

When the expanded ore is picked up from the furnace it is ready for grading and bagging. The plants have different methods of grading, depending on the uses to which the product is to be put.

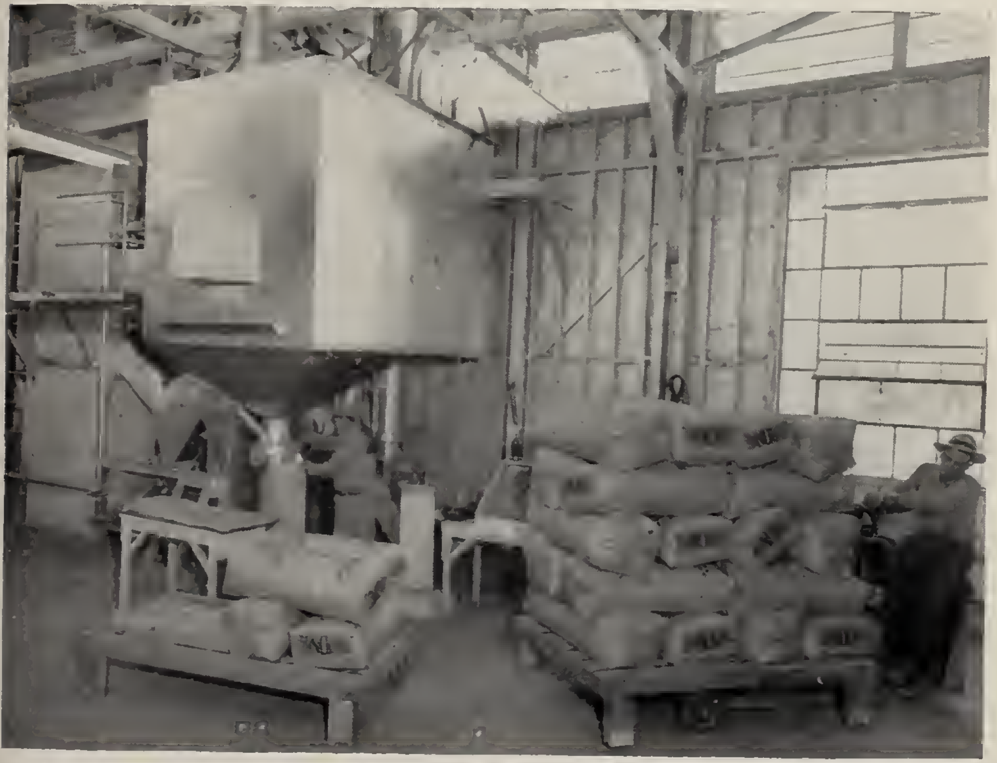

FIGURE 4. Processing and bagging vermiculite: On the left is the furnace used to expand vermiculite ore. The expanded ore is then elevated overhead into the loading hopper (center) below which the bags are filled and sealed.

One method is to lift the expanded ore to a long mesh screen set over the bagging hoppers. As the ore slides down the tilted screen, it passes over meshes of various sizes. The powder or very fine flakes drop through the fine mesh into the first hopper, larger flakes through the second size of mesh into another hopper, etc. Thus the expanded flakes can be graded into several sizes.

A second method of grading is by the use of forced air. As the granules leave the furnace and are elevated overhead, a fan drives the lighter and finer material across an opening into a hopper while the unwanted heavier granules and unexpanded gangue drop through the opening. This method is used when very fine ore is being fed into the furnace, thus producing little of the larger and heavier material after exfoliation. The average loss by this method is estimated to be about 5 percent.

Until the flakes reach the bagging hoppers the process is entirely automatic, except for furnace and machine tenders. Bagging, however, requires some hand labor. A 4-cubic-foot bag is placed under the spout extending from the bagging hopper. When the bag is filled it is removed by hand and sealed with gum tape or tie wires. One 4-cubic-foot bag of home insulation weighs approximately 25 pounds.

Since the exfoliating of vermiculite is a relatively simple operation, one or two foremen generally supervise the entire plant.

LABOR REQUIREMENTS

Three-fifths of the 19.2 man-hours required to process 1,000 cubic feet of expanded vermiculite in 1946 were needed for the most important operations of heating, grading, and bagging. An average of 25.2 man-hours was needed for all production operations, including the 6 man-hours for plant administration, clerical, and selling functions. Between individual plants, man-hour requirements for processing and administration ranged from 20.5 to 29.4 man-hours. This range was found to depend in large part on the degree to which the plants approached capacity operations. For example, plants operating on a three-shift basis required an average of 24 man-hours per 1,000 cubic feet of production, compared with the average of 29 man-hours required by plants operating fewer than three shifts.

It will be noted from table 8, that as much labor was needed to transport from mine to plant the 3.3 tons of ore used per 1,000 cubic feet of expanded vermiculite (19.4 man-hours), as was needed to process the ore (19.2 man-hours) when it arrived. The reason for this is the long haul, averaging 1,500 miles, from mine to the widely scattered plants, which are situated near their markets rather than near the few mine locations. Because of its light weight and consequent bulk, it is impracticable to ship the finished product any great distance. An average of only 13 tons, in fact, constitutes a fully loaded car. The average rail haul for the finished product is 200 miles, for which an estimated 4.7 man-hours[18] are required per 1,000 cubic feet of insulation.

---

[18] See footnote 11.

Table 8.—*Labor requirements for all operations in production and distribution of 1,000 cubic feet of vermiculite home insulation in 1946*

Operation	Man-hours per 1,000 cubic feet of the final product
Total—all operations	61.1
Extraction of ore [1]	8.9
Transportation of ore	19.4
Processing	19.2
Unloading raw materials	2.1
Heating, grading, and bagging	11.6
Loading	5.5
Administration, clerical and sales	6.0
Production of fuel used [2]	.7
Production of paper bags used [3]	2.2
Transportation of final product	4.7

[1] About 3.29 tons of ore are needed to produce 1,000 cubic feet of vermiculite home insulation.

[2] About 8.9 gallons of fuel oil at mine, 16.3 gallons of fuel oil at plant, and 25 kilowatt-hours of electric-power were required per 1,000 cubic feet of expanded vermiculite, taking, respectively, an estimated 0.2, 0.4, and 0.1 man-hours to produce.

[3] An estimated 250 paper bags were used per 1,000 cubic feet of expanded vermiculite produced. The estimate shown does not include the labor required to produce the paper used in the bags.

Nearly 9 man-hours are expended in producing 3.3 tons of ore in the mine, covering administration requirements as well as the mining, cleaning, screening, grading, and loading operations. Over a third of the mining man-hours are needed in mining the ore, and in preliminary crushing and sorting. Cleaning, screening, and grading the ore require nearly half the total man-hours. The remaining labor is needed for maintenance, clerical, and supervisory labor.

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington 25, D. C., May 8, 1948.

The Secretary of Labor:

I have the honor to transmit herewith a bulletin summarizing data on primary market prices during 1946. Preliminary mimeographed reports are released regularly, giving the current indexes and monthly prices from the primary market price series maintained by the Bureau. These reports are available upon request to persons having need for them.

This bulletin was prepared in the Prices and Cost of Living Branch, by Galen B. Price and Doris P. Rothwell, under the direction of Lester S. Kellogg, former Chief. Prices were collected under the supervision of Ethel D. Hoover, Chief. Consumers'Prices Division, and Jesse M. Cutts, Chief, Industrial Prices Division.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Bulletin No. 920 of the
United States Bureau of Labor Statistics

Wholesale Prices, 1946

Description and Use of BLS Primary Market Price Data

The primary market price data of the Bureau of Labor Statistics
epresent prices at primary market levels—that is, at the levels of the
rst commercial transaction for each commodity. A major propor-
on of the prices are selling prices of manufacturers or producers and
o not represent prices charged by wholesalers to retailers. Prices
re for commodities—tangible goods (except for gas and electricity);
ervices, real estate, transportation, and securities are not included.
he word "wholesale" used in connection with this index refers to
les in large lots.

Wherever feasible, prices are obtained f. o. b. point of production
sale unless an industry normally sells on another basis, e. g., de-
vered. For farm products, some foods, and certain industrial raw
aterials, BLS prices are those quoted in organized commodity mar-
ets. The price series maintained by the Bureau are defined in terms
a given specification including detailed description of the com-
odity at stated terms of trade and to a specific type of purchaser.
majority of the price series consist of 1 quotation from 1 seller, since
r many articles prices of major producers tend to move together.
or some commodities, however, quotations from as many as 50
llers may be averaged to give a representative price.

For most fabricated goods, prices are obtained directly from sellers.
or other commodities which have recognized markets, price quota-
ons are taken from trade journals.

THE WHOLESALE PRICE INDEX

The primary market price data collected by the Bureau are used in
aking a number of price indexes, of which the most important is the
holesale price index. This index is based on prices of about 850
ajor commodities combined into 49 subgroups, 10 major groups, and
economic groups. All types of commodities, from raw materials to
ished industrial and consumer goods, are represented. Indexes are
ublished monthly for all groups and subgroups but weekly only
r the 10 major groups and 5 economic groups. Because of differ-
ces in methods of calculation during earlier periods, the monthly

and weekly indexes are not directly comparable as to level. The weekly index, however, serves as an accurate indicator of the direction and magnitude of current price changes.

The wholesale price index is calculated as a fixed base weighted aggregate using prices in 1926 as 100. Quantity weighing factors for the index are based on market sales during the years 1929 and 1931, except for agricultural commodities, for which the average of the years 1929, 1930, and 1931 is used.

In computing the index, the current price for each commodity is multiplied by the quantity weighting factor, to give a value aggregate for that commodity. The sum of the value aggregates at current prices for all the commodities in each group is divided by the sum of the value aggregates at 1926 prices to give the index for each group on the 1926 base. Major changes in specifications of commodities, shifts in the relative importance of sales to different types of purchasers or by different types of sellers, and alterations in the distribution pattern of the industry are handled so as to cause no movement in the index. The relation of the value aggregate for each commodity expressed as a percentage of the value aggregate of all commodities in the index in 1946 is shown in table 12 under the heading "Relative importance, year 1946." The relative importance of each commodity in the index changes as the rate of price change varies among commodities, since it is based on the product of the quantity weighting factor and the current price. Thus, it may be different in the index for each period.

CONSTRUCTION OF SPECIAL INDEXES

Persons wishing to construct indexes for special commodity groups may do so by using the relative importance data in this volume for 1946 and the wholesale price series regularly published by the Bureau in printed or mimeographed reports, and the following procedure, for all periods since January 1939:

1. Convert the entire price series for each commodity to be included in the special group to ratios of the 1946 average prices (1946=100).
2. Multiply the ratio for each commodity for each period by the relative importance for 1946 shown for the commodity in table 12.
3. Total these products for each period.
4. Divide these totals by the sum of the relative importances of the commodities used. The result is a series of weighted indexes for the special commodity group, on the base 1946=100. These indexes may then be shifted to any other base period for which these special indexes have been computed, by the usual procedure.

Certain commodities are included in more than 1 commodity group and these duplications must be kept in mind in using this procedure for calculating special indexes. Thus prices of 23 commodities are ncluded in both the farm products and foods indexes, and prices of 3 other commodities are included in both the metals and metal roducts and building materials groups. The commodities so dupliated are listed in table 12 under the foods and building materials roups, with appropriate reference as to where price data are shown. These 46 commodities are counted only once in the all-commodities ndex. The relative importance figures shown in table 12 for the farm roducts and metals and metal products groups and subgroups nclude these duplicated commodities. The relative importance of he foods and building materials groups and subgroups do not include hese duplicated commodities.

The Bureau prepares several special purpose primary market price ndexes in addition to the wholesale price index. These indexes also re shown in this volume.

PURCHASING POWER OF THE DOLLAR

The purchasing power of the dollar is a concept in common use. It must be defined in terms of the commodities and services which are to be purchased, and clearly related to a stated base. It may be measured for a single commodity or for a large number of commodities taken together. As prices increase, the purchasing power of the dollar decreases, and vice versa.

Any of the indexes in this volume may be used to measure changes in the purchasing power of the dollar in terms of the commodities included in each index.

Changes in the purchasing power of the dollar may be derived from any of these price indexes by dividing the index number for the period selected as the basis for comparison by the index number for each of the other periods which is being compared with this base period. For example, the comprehensive wholesale price index was 107.1 in January 1946 and 140.9 in December 1946 (1926=100). Based on this index, the purchasing power of the January 1946 dollar was $0.76 in December 1946 $\left(\frac{107.1}{140.9}=0.76\right)$.

Summary of Primary Market Price Movements, 1946

Primary market prices advanced 31.6 percent during 1946, the largest increase in a single calendar year since World War I. In December 1946 the all-commodities wholesale[1] price index was 87.9 percent higher than in August 1939 at the beginning of the Second World War, and 33.3 percent above August 1945 when hostilities ceased.

---

[1] For a description of the Bureau of Labor Statistics wholesale price data, see p. 1.

The year 1946 was one of change in the pattern of market price activity. Industrial commodity prices, which had remained fairly stable after the United States entered the war, began to move up sharply during the early months of 1946 and showed advances exceeding those for agricultural commodities. Pressures toward higher prices were intensified in 1946 by strong demand, arising from the high level of national income and shortages of many basic materials and finished products. Foreign purchases rose after the war. Domestically, increases in the purchases of producers' durable goods and in the rate of consumer expenditures tended to offset declines in government spending. Although production reached peacetime levels in most industries, demand still exceeded the supply of available goods. Strikes in the steel and coal industries during the first half of the year and other work stoppages, including those arising out of shortages of key materials, hampered production.

During the first 6 months of 1946, ceiling increases were allowed by OPA for many manufactured goods to cover higher costs of materials and labor, to offset the elimination of subsidies, to restore profit margins, and to stimulate production. During this period, there was a great deal of price uncertainty as pressures for defeating impending price control legislation were increased. The Price Control Extension Act of 1946, passed by the Congress on June 28 to replace the act due to expire June 30, was vetoed on June 29 by the President with the statement that it "legalized inflation."

Prices of all goods and services except utilities and other public services were free from control from June 30 to July 25. During this period there were sharp increases in prices of agricultural commodities, but the possibility of resumption of price controls restrained advances for most industrial products.

The Price Control Extension Act of 1946, which became law on July 25, renewed, with certain exceptions, the controls in effect June 30 but specified that price controls and subsidies were to be terminated as soon as practicable and in no event later than June 30, 1947. The act established a Price Decontrol Board with final power to order removal or reestablishment of controls. Responsibility for control of agricultural prices was given to the Secretary of Agriculture, and only agricultural commodities certified by him as in short supply could be continued under control. By December 31, 1946, all commodities not important in relation to business costs or living costs were to be removed from control. In addition, commodities were to be removed from control as soon as supply was in approximate balance with demand.

Under this act, a number of commodities, including a large proportion of agricultural products, were specifically exempted from price control. These included:

1. Poultry, eggs, tobacco, and petroleum and their products, subject until August 21, 1946, to restoration of control by the Price Decontrol Board.

2. Livestock, meats, dairy products, grains, cottonseed, and soybeans and their products, which were exempted at least until August 21, 1946, subject to final decision by the Price Decontrol Board.

All of the commodities in the first group remained uncontrolled, since no action to restore them was ordered by the Board before August 21. On August 20, the Board ordered restoration of controls on livestock and meats, cottonseed, and soybeans and their products but continued to exempt grains and dairy products.

Reinstatment of subsidies in effect on June 29, 1946, was made subject to approval of the Price Decontrol Board. Moreover, all such programs including food subsidies were to be progressively reduced and terminated not later than April 1, 1947. Subsidies on meats were reinstated along with price controls, but those on dairy products, flour, processed vegetables, dried fruits, coffee, soybeans, and flaxseed were discontinued.

Restoration of controls slowed down the abrupt price rise, but the exemption of many important agricultural commodities caused a continued advance in agricultural prices. Following restoration of price controls and subsidies on livestock and meats on September 1, there were some price declines, but the advance was resumed in October as additional agricultural commodities were exempted from control. Prices of both farm products and foods reached peak levels for the year in November. Moreover, special provisions of the new act, which required ceiling increases for many articles, resulted in a steady rise in prices of industrial goods to the end of the year.

Commodities were decontrolled rapidly under the new act. In late September about 29 percent by value of all items in the wholesale price index, excluding gas and electricity, had been removed from OPA control. By mid-October most foods had been exempted from control, and on November 9 all price controls with the exception of those on rents, sugar, sirup, and rice were suspended by Presidential directive.

FARM PRODUCTS AND FOODS

Average prices of farm products and foods jumped 27.8 percent and 47.4 percent, respectively, from December 1945 to December 1946, in sharp contrast with the moderate advances of 4.8 percent for farm products and 2.9 percent for foods during 1945. As the year began, price increases were granted by OPA to compensate for discontinuation of subsidies as on butter and cheese, wage adjustments as on meats, and rising world prices as on sugar and pepper. On February 6 a nine-point program was announced controlling the distribution and use of grains in order to provide supplies for export, and the subsequent Government grain purchasing program upset domestic wheat and corn markets; some flour mills were forced to shut down, resulting in a temporary bread shortage in the spring. In May substantial upward ceiling adjustments for grains were effected under new parity ratios. During the spring, meats were scarcer than at any time during the war, and other commodities such as butter, margarine, and other fats and oils became increasingly scarce. There were widespread reports that commodities were being withheld from market as the date of expiration of the Price Control Act approached.

After the lapse of OPA on June 30, agricultural commodity prices surged upward as subsidy payments ceased and demand continued strong. The farm products index advanced 12.1 percent and foods 24.2 percent in July. From the end of June through August, livestock prices climbed rapidly despite unprecedented marketings, and meat prices rose nearly 80 percent. Controls were reimposed on these commodities at the end of August and shipments dropped sharply, causing a general meat shortage in September. The ensuing price decreases, though substantial, were short-lived and after most food controls were rescinded in mid-October, prices rose to new high levels. Prices quoted for good to choice beef steers at Chicago in November averaged $29.75 per 100 pounds as compared with $17.41 in June.

Also contributing to the sharp advances for prices of agricultural commodities over the year was the 58-percent rise in prices of dairy products, due in large part to the elimination of the dairy feed subsidy in late April. Cereals and bakery products, recontrolled in late July, were later granted substantial ceiling advances and rose after decontrol in late October to a point almost 50 percent higher than in December 1945. Milling of regular flour was resumed, following termination on September 1 of the 6 months' emergency order requiring 80 percent wheat extraction. Sugar, together with sirups and rice, remained under OPA control but continued to advance as the purchase price of Cuban sugar was linked to increases in the Bureau's retail price indexes under an agreement made between the Commodity Credit Corporation and Cuba in July. In November, farm products prices approximated the January 1920 peak and food prices reached an all-time high. However, prices dropped somewhat in December, reflecting increased supplies and consumer resistance.

HIDES AND LEATHER PRODUCTS

Of most importance in the 48.6-percent rise for hides and leather roducts from December 1945 to December 1946 were the increases of 4 percent for hides and skins and 78 percent for leather, over half of hich developed after decontrol of these commodities at the end of ctober. Some ceiling advances had been granted prior to June 30, ut the first major increases took place after the removal of foreign ides and raw goatskins from import controls and the temporary apse of ceilings at the end of June. There were roll-backs to June eilings for some leathers when price controls were restored, but rices resumed their rapid climb after October 30 with final decontrol. ompetition with foreign bidders and a shortage of hides and skins eputedly resulting from black-market operations in meats served to ustain high prices, although there was a weakening for hides and kins toward the end of the year. There was a rise of 34 percent in actory prices of shoes over the year, most of which occurred in the ast quarter following advances in leather and other costs. In ecember 1946, hides and leather products prices were over 90 percent igher than in August 1939.

TEXTILE PRODUCTS

Prices of textile products advanced 32.8 percent in 1946, increasing teadily with OPA ceiling adjustments, and later with strong demand nd limited supplies. During the first 6 months, higher ceilings were granted for men's and women's apparel to stimulate production of carce items, and clothing prices advanced 12 percent. Prices of otton goods were adjusted under the Bankhead Amendment to the Stabilization Extension Act and were 11 percent higher in June 1946 han in December 1945. Further increases were necessitated by ising costs of raw cotton after June 30. In the second quarter, rices of raw cotton reached the highest point in over 20 years and ontinued to advance to nearly 39 cents a pound in October, when iquidation of speculative holdings caused a sharp break in the cotton market. The rise in prices of clothing and cotton goods continued fter the decontrol order in November, and in December prices were 21 and 45 percent higher, respectively, than in December 1945. The selling price of domestic raw wool was lowered by the Commodity Credit Corporation in the first quarter of 1946 to encourage purchases by manufacturers but was raised in the last quarter in accordance with parity ratios. Prices of woolen and worsted goods remained steady through July, advancing only moderately thereafter.

The first postwar imports of raw silk were offered for sale by the United States Commercial Company in July. Prices acceptable to the Government ranged well above prewar levels. Prices were lowered at subsequent auctions, as manufacturers hesitated to buy the raw silk in the face of consumer resistance to high prices of silk products in comparison with rayon and nylon goods.

BUILDING MATERIALS

The huge demand for building materials in conjunction with the housing program was an important factor in the price rise of 32 percent for building materials during 1946, more than half of which occurred in November and December after price decontrol. Higher ceilings were allowed by OPA prior to decontrol to cover costs and to stimulate production, particularly of lumber. It was reported during the first months of the year that much lumber was being sold through black markets. By the end of June, reported lumber prices were almost double their prewar average. Prices of plumbing and heating equipment were more than 11 percent higher than in December 1945.

During the period of uncontrolled prices in July, paint and paint materials was the only group to show significant price advances, with an increase of 6 percent. Following decontrol in November, prices of raw materials used in paints climbed to new highs with increases of 90 percent for linseed oil and 63 percent for ethyl acetate. Lumber prices continued to advance throughout the year, and at the close of the year quoted mill prices were the highest on record, 44 percent above December 1945.

Production of most building materials, although for some commodities above prewar levels, remained insufficient. In August a system of incentive premium payments was begun covering such items as hardwood flooring, brick, softwood plywood, gypsum paper liner, convector radiation, cast-iron soil pipe, and nails.

CHEMICALS AND ALLIED PRODUCTS

Chemicals and allied products prices as a group fluctuated moderately until after the removal of price controls in November, and then rose sharply. At the close of 1946, prices were 30.8 percent higher than in December 1945. There were large increases for a few commodities beginning in the spring, and during the temporary lapse of OPA in July prices for fats and oils and fertilizer materials advanced substantially. After decontrol, prices of many basic materials were advanced to cover higher production costs, and prices of derived products subsequently were increased. Drug and pharmaceutical materials reached all-time peaks in November and December, and fats and oils prices in December 1946 were twice as high as a year earlier.

METALS AND METAL PRODUCTS

The advance in prices of metals and metal products (27.6 percent r the year) began in the first quarter when OPA raised ceiling prices n steel an average of $5 per ton by order of the Stabilization Adminis- ator, to permit higher wages and to end the strike of steel mill workers hich was seriously hampering the reconversion program. This was llowed in the spring by ceiling increases in other basic metals, farm achinery, and plumbing and heating supplies, all reflecting the new age-price policy under which OPA was directed to give consider- tion to industry requests for price increases to relieve hardships rising from approved wage adjustments. Prior to decontrol, ceilings r copper, lead, and zinc were advanced. The shortages in these etals became more acute during the lapse of OPA controls and ubsidies in July, with trading virtually at a standstill. The price of ilver was raised to 90½ cents per ounce by Congress in July, and RFC urchase prices for lead and tin were raised with increases in world arkets. After controls were terminated in November, there were urther sharp increases for basic nonferrous metals. Iron and steel rices continued to advance, and many other commodities were ad- anced in price to cover higher material and labor costs. Production f motor vehicles reached prewar rates in October, permitting reintro- uction of current prices into the wholesale price index. In December, rices were 34 percent above April 1942 when civilian production as discontinued.

FUEL AND LIGHTING MATERIALS

Advances for fuel and lighting materials, housefurnishing goods, nd miscellaneous commodities were smaller, ranging around 15 ercent. Higher bituminous coal and anthracite prices were granted y OPA in late June to compensate producers for wage increases hich followed the work stoppage in the spring. Production was urtailed again in November when there was a general strike in soft oal mines, but miners returned to work under terms of the "Krug- ewis agreement," which had become effective in May. Following pecific exemption of petroleum and petroleum products from price ontrol in late July under the new act, prices of crude oil and petroleum roducts rose sharply, increasing nearly 25 percent over the year. As rices advanced, RFC subsidies to stripper-well producers were ithdrawn.

HOUSEFURNISHING AND MISCELLANEOUS GOODS

Housefurnishing goods prices advanced steadily and moderately uring 1946, for the most part following OPA adjustments, and there was much improvement in the supply of these commodities. The paper shortage of previous years continued through 1946. Prices for paper and its basic products were advanced by OPA and continued their upward trend following decontrol. There were advances in other miscellaneous commodities as well, particularly soap and cattle feed. However cattle feed quotations declined substantially late in the year, because of decreased demand and increased availability of feed corn.

Primary Market Prices—Index Numbers, by Groups and Subgroups of Commodities

Index numbers of primary market prices by groups and subgroups of commodities are shown for each month and the year 1946 in table 1, and for selected years in table 2. The commodities included in the groups "Raw materials," "Semimanufactured articles," and "Manufactured products" are listed on pages 8 and 9 of Wholesale Prices, 1944 (Bull. No. 870). These indexes are published regularly in monthly mimeographed reports and in the Monthly Labor Review.

TABLE 1.—*Index numbers of primary market prices, by groups and subgroups of commodities, 1946*

---

[1] The rate of production of motor vehicles in October 1946 exceeded the monthly average rate of civilian production in 1941, and in accordance with previous announcements the Bureau introduced current prices for motor vehicles in the October calculations. During the war, motor vehicles were not produced for general civilian sale, and the Bureau carried April 1942 prices forward in each computation through September 1946.

If April 1942 prices of motor vehicles had been used after September 1946, the indexes (1926=100) for the groups of which motor vehicles is a component would have been as follows:

	October	*November*	*December*	*Year*[2]
All commodities	132.5	137.9	139.0	120.7
Metals and metal products	114.3	117.0	120.5	112.3
Manufactured products	127.0	131.7	132.5	115.4
All commodities other than farm products	125.1	130.7	132.4	114.3
All commodities other than farm products and foods	121.6	117.8	121.6	108.8

[2] Not available.

[3] Revised.

Weekly Fluctuations in Primary Market Prices

Weekly index numbers of primary market prices by groups of commodities during 1946 are shown in table 3. These indexes are computed from 1-day-a-week prices to show week-to-week fluctuations. They are not directly comparable with the monthly primary market indexes given in tables 1 and 2. (For explanation see p. 1.) These indexes are issued in a regular weekly release available on Thursday for the previous week.

TABLE 3.—*Weekly index numbers of commodity prices in primary markets, by groups of commodities, 1946*

Daily Index of Spot Primary Market Prices of 28 Commodities

Daily index numbers based on spot primary market prices of 28 commodities for the period January 1 to December 31, 1946, are given in table 4.

These index numbers show the daily movements of prices of 28 selected commodities as quoted on organized exchanges and in primary markets. The daily index is more sensitive to changes in market conditions than is the Bureau's comprehensive wholesale price index, which includes many fabricated and semifabricated goods whose prices fluctuate less frequently and within narrower ranges. It differs from and should not be used as a substitute for the monthly consumers' price index, which measures changes in the retail prices of goods and services purchased by moderate income families. The daily index is calculated as an unweighted geometric mean of the individual price ratios.[1] It is computed with the average of daily prices in August 1939 as the base in order to facilitate comparisons with prices prevailing in world markets just before the beginning of World War II. Prior to October 1946 this index was called the Daily Index of 28 Basic Commodities. The index is available each weekday, except Saturday, at 6 p. m. by telephone or by collect telegram. A release showing figures for the current week is issued each Friday.

A list of the 28 commodities included in the index is given below:

Wheat, average, per bushel:
  No. 2 hard winter, Kansas City.
  No. 2 dark northern spring, Minneapolis.
Flaxseed, No. 1, per bushel, Minneapolis.
Barley, good, malting, per bushel, Minneapolis.
Corn, No. 3 yellow, per bushel, Chicago.
Butter, extra, 92 score, per pound, Chicago.
Tallow, packers' prime, per pound, Chicago.
Hogs, good to choice, 200–220 pounds, per 100 pounds, Chicago.
Steers, good, 900–1,100 pounds, per 100 pounds, Chicago.
Lard, prime steam, per pound, Chicago.
Sugar, raw, 96°, duty paid, per pound, New York.
Coffee, Santos, No. 4, per pound, New York.
Cocoa beans, Accra, per pound, New York.
Shellac, T. N., per pound, New York.
Rubber, plantation, ribbed, s. s., per pound, New York.
Hides, cow, light native packers,' per pound, Chicago.
Rosin, "H" grade, per 100 pounds, Savannah.
Cottonseed oil, prime summer bleachable, per pound, New York.
Print cloth, 38½-inch, 64 by 60, 5.35 yards to pound, per yard, New York.
Silk, raw, Japan, 13–15 denier, 78 seriplane, per pound, New York.
Wool tops, spot market, per pound, New York.
Burlap, 10-ounce, 40-inch, per yard, New York.
Cotton, middling, 15/16 inch staple, per pound, average 10 spot markets.
Steel scrap, heavy melting, per ton:
  Chicago.
  Philadelphia.

---

[1] This means that a 10-percent rise in the price of sugar, which on August 30, 1946, was 4.2 cents per pound, has the same effect on the index as a 10-percent rise in steers which on the same date sold for $21.25 per 100 pounds. The index should therefore not be confused with a simple aggregate of actual prices, in which steers would have several hundred times the weight of sugar.

Tin, Grade A, 99.8 percent or higher, pig, per pound, New York.
Copper, electrolytic, ingot, per pound, New York.
Lead, desilverized, pig, open market, per pound, New York.
Zinc, prime western, pig, per pound, New York.

The index of 28 daily commodities is broken down into 5 major groups. These groups and the commodities falling under each group are as follows:

Import Commodities

Flaxseed
Sugar
Coffee
Cocoa beans
Shellac
Rubber
Hides
Silk
Wool tops
Burlap
Tin

Domestic Commodities

Wheat
Barley
Corn
Butter
Tallow
Hogs
Steers
Lard
Rosin
Cottonseed oil
Print cloth
Cotton
Steel scrap:
  Chicago
  Philadelphia
Copper
Lead
Zinc

Domestic Agricultural Commodities

Barley
Wheat
Corn
Hogs
Steers
Wool tops
Cotton

Foodstuffs

Wheat
Barley
Corn
Butter
Tallow
Hogs
Steers
Lard
Sugar
Coffee
Cocoa beans
Cottonseed oil

Raw Industrial

Flaxseed
Shellac
Rubber
Hides
Rosin
Print cloth
Silk
Wool tops
Burlap
Cotton
Tin
Copper
Lead
Zinc
Steel scrap:
  Chicago
  Philadelphia

On January 1, 1946, the daily index stood at 187.1. By the end of the year it had moved up to 303.9, an increase of 62.4 percent. From January 1 to June 29, 1946, the last day before the temporary suspension of OPA controls, prices of the 28 commodities moved upward only 6.6 percent. However, during the period of suspension between June 29 and July 25 prices moved upward by 24.8 percent. On November 9, 1946, when the President removed all but a few price controls the index stood at 276.1. By December 31 it had risen an additional 10.1 percent.

TABLE 4.—*Daily indexes of spot market prices of 28 commodities*

Revised Wholesale Price Series for Gas

In the 1926–27 revision of the Bureau's comprehensive primary market (wholesale) price index, a series of prices for manufactured gas was developed and introduced for the first time into the index. The series was carried back to 1913 as one of the subgroups of the fuel and lighting materials group. In 1928 the series was expanded to include prices for natural and mixed gas and the indexes were revised back to 1926. With the effective cooperation of the gas industry through its trade association and the Federal Power Commission, the Bureau of Mines, and the Division of Statistical Standards of the Bureau of the Budget, an extensive revision was made in the wholesale price series for gas and introduced in the calculation of the comprehensive index in March 1946.

FORMER SERIES

Prior to the revision, the gas composite represented average sales realization values (prices) per thousand cubic feet for (1) all sales of natural gas to all types of consumers by 20 producing or distributing companies in 19 cities and (2) all sales of manufactured and mixed gas to all types of consumers by 27 manufacturing or distributing companies in 27 cities. Sales realization value was obtained by dividing the combined revenue from sales of natural gas and manufactured and mixed gas by the combined sales expressed in thousand cubic feet.

The realized value represented rates and quantities at different levels of sale under different conditions of sale and without clearly defined specifications for the product. Fluctuations in any of these factors caused variations in the realization values, which were influenced by shifts in distribution to the different types of customers and were not due to changes in established gas rates. Also, the average value based on cubic feet did not take account of the heating content of the gas.

REVISED SERIES

The revised series represents weighted average realized values (prices) per dekatherm (1 million B. t. u.) for gas to industrial consumers and for electric power generation, adjusted for seasonal variation. Complete specifications are:

Code No. 354.1–A—Gas, manufactured and mixed; weighted average realized price per dekatherm (1 million B. t. u.), adjusted for seasonal variation, utility to all industrial consumers including sales for electric power generation; monthly from 24 utilities as reported to the Bureau through its association.

Code No. 354.1–B—Gas, natural; weighted average realized price per dekatherm (1 million B. t. u.), adjusted for seasonal variation, utility to all industrial consumers including sales for electric power generation; monthly from 25 utilities, as reported to the Bureau through its association.

The revised sample of respondents represents more than 60 percent of total United States sales of gas, in both quantity and revenue, to industry and for electric power generation. To obtain the average price for the country as a whole, the average realized price for each of seven geographic regions is weighted by the gas consumption in 1941 in the region, for each type of gas (natural or manufactured and mixed), separately.

Prices are expressed in dollars per million British thermal units (or per dekatherm), a basis of pricing which converts all types of gas to a common unit and allows computation of accurate composites for gas of varying heat content. Prices are adjusted for seasonal variation according to data reported to the industry association for the period 1939-44. It is planned to review these seasonal indexes in 1950, using data for a selected postwar period.

The revised series was incorporated in the calculation of the index for March 1946 with the customary lag of 1 month, using February prices. The revised series was introduced into the index at the same level as the former series, and no revision of previous data was made. The changed specifications are expected to minimize fluctuations in the realized prices resulting from seasonal changes in the volume of consumption and from shifts in the relative importance of industrial, commercial, and residential consumers who purchase gas at widely different rates.

In addition to the composite series for all gas meeting these specifications, composite average prices will be published separately for manufactured and mixed gas and for natural gas.

Revision of Prices and Index Numbers for Motor Vehicles

During the war, motor vehicles (passenger cars and trucks) were not produced for general civilian sale and the Bureau carried forward the April 1942 prices in the computation of the primary market (wholesale) price index. October 1946 production exceeded the 1941 monthly average production (for general civilian sale), and current prices for motor vehicles were reintroduced into the index calculations as of that month. With this reintroduction at currently prevailing prices a revision was made in both the passenger car and truck indexes, involving the type of prices used and the product and company samples.

An advisory committee consisting of technical representatives of the various automobile companies and the industry association cooperated with and advised the Bureau in this revision.

FORMER PASSENGER CAR PRICE INDEX

Passenger cars were included in the comprehensive primary market price index for the first time in the 1926–27 general revision. Prices and indexes were carried back to 1913 and were included as a subgroup of the metals and metal products group. The former index for passenger cars was a weighted series based on average prices of two low-priced, two medium-priced, and two high-priced makes. For all makes except one of the low-priced cars, the price included in the composite series was a simple arithmetic average of the quotations for all models and body types selling below $4,000. In the case of the one low-priced make, the price used was a weighted average of prices of the two-door and four-door sedans and the business coupe. The index was subject to the criticisms (1) that the sample included some makes which were unimportant in terms of dollar sales volume while omitting other makes which had assumed considerable importance, (2) that the less popular body types were equally as important in the index as were the volume selling body types, (3) that the quotations used in the calculation were factory delivered prices and not primary market (wholesale) prices, and (4) that little or no adjustment was made for specification changes.

REVISED PASSENGER CAR INDEX

The revised passenger car index is made up of two composite price series, one for low-priced cars and the other for medium-priced cars, weighted by total new car registrations in 1941.

The composite for low-priced cars includes three popular makes of two-door sedans produced by three large manufacturers. The composite for medium-priced cars includes four makes of the volume selling four-door sedans produced by two large and two representative smaller companies.

Each make of car in the lower-price category is weighted either by the total number of cars of that make produced or by those produced in that price class by each of the three large manufacturers in 1941. The cars selected for the sample in the medium-price field, which are produced by the two large companies, are assigned the total weight of all cars produced by these manufacturers outside the low-price field. The two medium-priced cars selected for the sample, which are produced by two smaller manufacturers, are assigned the weight of all cars produced in all price ranges by all of the smaller manufacturers, with their importance divided equally between the two makes priced for the index. The seven makes included in the revised index account directly for nearly 80 percent of all new car sales in 1941 and indirectly for all new car sales in that year. In the revision, manufacturers' net selling prices to direct dealers are used. This revision does not meet all of the criticisms of the former index, but it does make substantial progress in improvement in an uncharted statistical field.

FORMER TRUCK PRICE INDEX

Trucks were included in the comprehensive primary market price index for the first time in the 1930–31 general revision. Prices and indexes were carried back to 1926 and were combined with passenger cars to form the motor vehicle subgroup of the metals and metal products group.

The former truck index was computed from prices of 76 models grouped in three composite series: ¾ ton and less, 1 ton and less than 2 tons, and 2 to 3½ tons. The makes of trucks included in the above groupings were limited to the product of three manufacturers. The verage price of each capacity group was weighted in accordance ith its relative importance to all new trucks, on the basis of regis- ations. This index was subject to the same criticism as the index r passenger cars.

REVISED TRUCK INDEX

The revised truck index represents prices from 10 manufacturers, rouped into 6 classes, each covering a different range of gross vehicle eights. These ranges are as follows:

	Range of gross vehicle weights
Class 1	5,000 pounds and less.
Class 2	5,001 pounds to and including 10,000 pounds.
Class 3	10,001 pounds to and including 14,000 pounds.
Class 4	14,001 pounds to and including 16,000 pounds.
Class 5	16,001 pounds to and including 19,500 pounds.
Class 6	19,501 pounds and over.

The total registration of all new trucks in 1941 was used as the asis for weighting. Total registrations were distributed according gross vehicle weight and each make was assigned a value in accord- nce with its relative importance in total production during the period 936–40. The prices used were manufacturers' net prices to direct ealers.

Method of introduction.—Since the revised series for passenger cars nd trucks were not comparable with the former series, the following rocedure was used in introducing the revised series into the index. rices on the new series were obtained back to December 1941. The evised subgroup aggregates (sum of products of prices and quantity eights) for December 1941 were made identical with the former ubgroup aggregates for the same date by means of a conversion actor. Consequently for all dates subsequent to December 1941, evised aggregates for the "motor vehicles" subgroup, after adjust- ent by the conversion factor, are comparable with aggregates used rior to the revision. The revised indexes are then derived in the ustomary manner by dividing the adjusted aggregates by the 1926 ase period aggregate.

In the calculation of the October 1946 indexes (the effective date of he reintroduction) the total increase in price since December 1941 for otor vehicles was reflected, and this affected several groups of the ureau's comprehensive primary market price index. Certain of the roup indexes were in use for contract adjustments, and special in- exes for the affected groups were calculated which continued to use he April 1942 prices. These indexes have been continued and will be ublished as long as the need for them exists. The regularly com- uted indexes using current prices are given in table 1.

The monthly indexes for the affected groups from October to December 1946, inclusive, using April 1942 prices for motor vehicles, were as follows:

	Indexes (1926=100), using April 1942 prices for motor vehicles		
	October 1946	*November 1946*	*December 1946*
All commodities	132.5	137.9	139.0
Metals and metal products	114.3	117.0	120.5
Manufactured products	127.0	131.7	132.5
All commodities other than farm products	125.1	130.7	132.4
All commodities other than farm products and foods	113.2	117.8	121.6

The revised indexes of passenger cars, trucks, and motor vehicles combined are available back to 1942 and provide a comparable series of indexes for passenger cars and trucks since January 1926 and for motor vehicles since January 1913.

Soap—Indexes of Primary Market Prices

Because of special interest in price movements for soap, the Bureau has prepared a special index of primary market prices of soap. The commodities included in this index are those included in the comprehensive wholesale price index of the Bureau, as listed in table 12, Primary Market Prices, Index Numbers, and Relative Importance of Individual Commodities (codes 773–1 through 777–3.1). Annual indexes from 1926 through 1946 and monthly indexes from January 1933 through December 1946 are shown in the following table.

TABLE 5.—*Indexes of primary market prices of soap*

[1926=100]

Year	January	February	March	April	May	June	July	August	September	October	November	December	Average
1926	------	------	------	------	------	------	------	------	------	------	------	------	100.0

Wood Pulp, Paperboard, and Paper—Indexes of Primary Market Prices

The Bureau has prepared separate indexes of primary market prices for three subgroupings of the paper and pulp subgroup in the comprehensive wholesale price index—wood pulp, paperboard, and paper—to give more detailed information on price movements for various types of paper and pulp products. The price series and weighting factors used in the calculation of these indexes are those used in the computation of the index numbers for paper and pulp. (See mimeographed report LS 46–2471, April 1, 1946.) Annual indexes from 1926 through 1945 and monthly indexes from January 1933 through December 1945 are shown in table 6. Indexes for 1946 are shown in table 12, Primary Market Prices, Index Numbers, and Relative Importance of Individual Commodities.

TABLE 6.—*Index numbers of primary market prices of paper and pulp, by groups*

[1926=100]

Year and month	Paper and pulp	Wood-pulp	Paper-board	Paper

Prepared Paint and Paint Materials—Indexes of Primary Market Prices

To show the price movements for prepared paint as contrasted with paint materials, the Bureau has prepared separate index numbers for these groups, as a break-down of the paint and paint materials subgroup of the comprehensive wholesale price index. The price series and weighting factors used in the calculation of these indexes are those used in the computation of the index numbers for paint and paint materials. (See mimeographed report LS 47–3806, June 16, 1947). Table 7 shows annual indexes from 1926 and monthly indexes from January 1935. Indexes for 1946 are shown in table 12, Primary Market Prices, Index Numbers, and Relative Importance of Individual Commodities.

TABLE 7.—*Index numbers of primary market prices of paint and paint materials, by groups*

[1926=100]

Year and month	Paint and paint materials	Prepared paint	Paint materials

Waste and Scrap Materials—Indexes of Market Prices

Index numbers showing changes in market prices for waste and scrap materials for 1946, by groups of commodities and by weeks, are shown in table 8. Calculation of these indexes, prepared at the request of war agencies of the Federal Government, was discontinued at the end of 1946. A mimeographed statement is available upon request, giving a description of the 44 materials included in the indexes and weekly indexes back to January 1939. Indexes prior to 1946 have been published in previous wholesale prices publications, beginning with Wholesale Prices, October 1941 (Serial No. R. 1407). That publication also lists the commodities included in the indexes.

TABLE 8.—*Index numbers of market prices of waste and scrap materials*

Standard Machine Tools—Indexes of Prices

Table 9 shows monthly index numbers of prices of 11 types of standard nonspecialty machine tools for 1946. Comparable data back to January 1937 have been given in previous wholesale price publications, beginning with Wholesale Prices, June 1941 (Serial No. R. 1349).

TABLE 9.—*Index numbers of prices of standard machine tools, 1946*

[August 1939=100]

Month	General index	Boring mill, vertical	Drill, radial	Drill, upright	Grinding machine, cylindrical type	Lathe, engine	Lathe, turret, for bar stock	Milling machine	Planer	Punch press	Screw machine, automatic, for bar stock	Shaper, horizontal type

Construction Machinery—Indexes of Manufacturers' Prices

Index numbers of manufacturers' prices of construction machinery are shown by months and for the year 1946 in table 10. A description of the 60 types of construction machinery included in the index and comparable data back to August 1939 are given in Wholesale Prices, 1944 (Bull.No. 870).

TABLE 10.—*Index numbers of manufacturers' prices of construction machinery, 1946* [1]

[August 1939=100]

Year and month	All groups	Group I	Group II	Group III	Group IV	Group V	Group VI	Group VII	Group VIII	Group IX
Average for year	120.8	116.6	120.9	114.2	128.4	120.1	115.5	107.3	128.6	104.1

[1] Group I—Construction equipment, tractor mounted; Group II—Construction machinery, specialized; Group III—Construction material mixers, pavers, spreaders and related equipment; Group IV—Construction material processing equipment; Group V—Power cranes, draglines, shovels, and related equipment; Group VI—Scrapers, maintainers and graders; Group VII—Drilling and boring machinery; Group VIII—Tractors, track type; Group IX—Portable air compressors.

General and Auxiliary Machinery and Equipment—Indexes of Manufacturers' Prices

Monthly and yearly indexes of manufacturers' prices of general and auxiliary machinery and equipment for 1946 are shown in table 11.

A description of this index and the monthly and yearly data, back to 1939, are given in Wholesale Prices, 1945 (Bull. No. 877).

Primary Market Prices, Index Numbers, and Relative Importance of Individual Commodities

Monthly and annual average prices in 1946 for commodities included in the wholesale price index, plus a small number of additional commodities selected because of special importance in particular fields, are shown in table 12.

Changes in specifications are indicated by changes in the digit following the decimal in the code number assigned to the commodity. Such changes are handled so that the individual commodity indexes, but not the prices, for the new specification generally are comparable with those for the old specification.

The average prices shown are averages of 1-day-a-week quotations from one or more sellers of the commodity described. In general, the prices are those charged by manufacturers or producers, or prevailing in primary commodity markets.

Prices are "net" after the deduction of applicable discounts.

The meaning and use of the data in the column "Relative importance, year 1946" are discussed on page 2. In 1946, raw materials had a relative importance of 32.90 percent of all commodities, semimanufactured articles 7.65 percent, and manufactured products 59.45 percent.

---

[1] Base period price not available.

[2] Insufficient data.

[3] New series.

[4] Reintroduction of earlier specifications. (During the war period, prices on a substitute series of different specifications were used to represent price movements of this commodity. The substitute series has now been replaced by the series formerly used.)

[5] 1935-39=100.

[6] Less than 0.005

[7] Not included in wholesale price index.

[8] Includes tax of $17.10 per gallon.

[9] Indexes for this article of furniture are based on prices for a number of qualities, materials, finishes, and size. Average prices for combinations of such different specifications are not meaningful, and therefore are not shown. Price changes due solely to changes in specifications are handled so that they do not affect the index for the commodity.

[10] Average of 11 months.
